## Generalized Symmetric-Definite Eigenvalue Problems: ScaLAPACK Computational Routines

This section describes ScaLAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see LAPACK[Generalized Symmetric-Definite Eigenvalue Problems](#)) to standard symmetric eigenvalue problem  $Cy = \lambda y$ , which you can solve by calling ScaLAPACK routines (see [Symmetric Eigenproblems](#)).

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists these routines.

### Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

| Operation                   | Real symmetric matrices | Complex Hermitian matrices |
|-----------------------------|-------------------------|----------------------------|
| Reduce to standard problems | <a href="#">p?sygst</a> | <a href="#">p?hegst</a>    |

### p?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

### Syntax

```
void pssygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
float *scale , MKL_INT *info);
void pdsygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
double *scale , MKL_INT *info);
```

### Description

The [p?sygst](#) function reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following *sub(A)* denotes  $A(ia:ia+n-1, ja:ja+n-1)$  and *sub(B)* denotes  $B(ib:ib+n-1, jb:jb+n-1)$ .

If *ibtype* = 1, the problem is

$$\text{sub}(A)*x = \lambda * \text{sub}(B)*x,$$

and  $\text{sub}(A)$  is overwritten by  $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$ , or  $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ .

If  $\text{ibtype} = 2$  or  $3$ , the problem is

$\text{sub}(A) * \text{sub}(B) * x = \lambda * x$ , or  $\text{sub}(B) * \text{sub}(A) * x = \lambda * x$ ,

and  $\text{sub}(A)$  is overwritten by  $U * \text{sub}(A) * U^T$ , or  $L^T * \text{sub}(A) * L$ .

$\text{sub}(B)$  must have been previously factorized as  $U^T * U$  or  $L * L^T$  by `p?potrf`.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Description

The p?hegst function reduces complex Hermitian positive-definite generalized eigenproblems to the standard form.

In the following sub(*A*) denotes *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) and sub(*B*) denotes *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*n*-1).

If *ibtype* = 1, the problem is

$$\text{sub}(A)*x = \lambda * \text{sub}(B)*x,$$

and sub(*A*) is overwritten by  $\text{inv}(U^H)*\text{sub}(A)*\text{inv}(U)$ , or  $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^H)$ .

If *ibtype* = 2 or 3, the problem is

$$\text{sub}(A)*\text{sub}(B)*x = \lambda*x, \text{ or } \text{sub}(B)*\text{sub}(A)*x = \lambda*x,$$

and sub(*A*) is overwritten by  $U*\text{sub}(A)*U^H$ , or  $L^H*\text{sub}(A)*L$ .

sub(*B*) must have been previously factorized as  $U^H*U$  or  $L*L^H$  by p?potrf.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ibtype</i> | (global) Must be 1 or 2 or 3.<br>If <i>itype</i> = 1, compute $\text{inv}(U^H)*\text{sub}(A)*\text{inv}(U)$ , or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^H)$ ;<br>If <i>itype</i> = 2 or 3, compute $U*\text{sub}(A)*U^H$ , or $L^H*\text{sub}(A)*L$ .                                                                                                                                                                                                                                                                                                                                                                        |
| <i>uplo</i>   | (global) Must be ' <i>U</i> ' or ' <i>L</i> '.<br>If <i>uplo</i> = ' <i>U</i> ', the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $U^H*U$ .<br>If <i>uplo</i> = ' <i>L</i> ', the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L*L^H$ .                                                                                                                                                                                                                                                                                                                    |
| <i>n</i>      | (global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ( $n \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>a</i>      | (local)<br>Pointer into the local memory to an array of size $l1d\_a*LOCc(ja+n-1)$ . On entry, the array contains the local pieces of the $n$ -by- $n$ Hermitian distributed matrix $\text{sub}(A)$ . If <i>uplo</i> = ' <i>U</i> ', the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = ' <i>L</i> ', the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>desca</i>  | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>b</i>      | (local)<br>Pointer into the local memory to an array of size $l1d\_b*LOCc(jb+n-1)$ . On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by <a href="#">p?potrf</a> .                                                                                                                                                                                                                                                                                                                                                                         |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>descb</i>  | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Output Parameters

|              |                                                                                                                                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i>     | On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as $\text{sub}(A)$ .                                                                                                                             |
| <i>scale</i> | (global)<br>Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this function. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement. |
| <i>info</i>  | (global)                                                                                                                                                                                                                        |

If  $info = 0$ , the execution is successful. If  $info < 0$ , if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j - 1$ , had an illegal value, then  $info = -(i*100+j)$ ; if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## Description

The `p?geevx` function computes for an  $n$ -by- $n$  real/complex non-symmetric matrix  $A$ , the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (`ilo`, `ihi`, `scale`, and `abnrm`), reciprocal condition numbers for the eigenvalues (`rconde`).

The right eigenvector  $v$  of  $A$  satisfies

$$A \cdot v = \lambda \cdot v$$

where  $\lambda$  is its eigenvalue.

The left eigenvector  $u$  of  $A$  satisfies.

$$u^H A = \lambda u^H$$

where  $u^H$  denotes the conjugate transpose of  $u$ . The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation  $D^H A D$ , where  $D$  is a diagonal matrix, to make its rows and columns closer in norm and the condition number of its eigenvalues smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic, but diagonal scaling will.

---

### NOTE

The current version doesn't support computation of the reciprocal condition numbers for the right eigenvectors.

---

## Current Notes and Restrictions

All the `p?geevx` interfaces call `p?lahqr` for computing eigenvalues and eigenvectors of the Hessenberg matrices. There are several restrictions for the usage of `p?lahqr`, which include:

- The current implementation of `p?lahqr` requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size.

- The current implementation of `p?lahqr` requires that input matrix  $A$ , the left and right eigenvector matrices  $VR$  and/or  $VL$  to be distributed identically and have identical context.

## Parameters

`balanc`

(global). Must be '`N`', '`P`', '`S`', or '`B`'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.

If `balanc` = '`N`', do not diagonally scale or permute;

If `balanc` = '`P`', perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale;

If `balanc` = '`S`', diagonally scale the matrix, that is, replace  $A$  by  $D^*A^*\text{inv}(D)$ , where  $D$  is a diagonal matrix chosen to make the rows and columns of  $A$  more equal in norm. Do not permute;

If `balanc` = '`B`', both diagonally scale and permute  $A$ .

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

`jobvl`

(global). Must be '`N`' or '`V`'.

If `jobvl` = '`N`', left eigenvectors of  $A$  are not computed;

If `jobvl` = '`V`', left eigenvectors of  $A$  are computed.

If `sense` = '`E`', then `jobvl` must be '`V`'.

`jobvr`

(global). Must be '`N`' or '`V`'.

If `jobvr` = '`N`', right eigenvectors of  $A$  are not computed;

If `jobvr` = '`V`', right eigenvectors of  $A$  are computed.

If `sense` = '`E`', then `jobvr` must be '`V`'.

`sense`

(global). Must be '`N`' or '`E`'. Determines which reciprocal condition numbers are computed.

If `sense` = '`N`', none are computed.

If `sense` = '`E`', computed for eigenvalues only.

`n`

(global) The order of the distributed matrix  $A$  ( $n \geq 0$ ).

`a`

(local)

Pointer into the local memory to an array of size  $\text{lld}_a * \text{LOCc}(n)$ . On entry, this array contains the local pieces of the  $n$ -by- $n$  general distributed matrix  $A$  to be reduced.

`desca`

(global and local) array of size `dlen_`. The array descriptor for the distributed matrix  $A$ .

`wr, wi`

(global output) Arrays, size at least  $\max(1, n)$  each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

**Description**

The p?gesvfunction computes the solution to a real or complex system of linear equations  $\text{sub}(A) * X = \text{sub}(B)$ , where  $\text{sub}(A) = A(i_a:i_a+n-1, j_a:j_a+n-1)$  is an *n*-by-*n* distributed matrix and  $X$  and  $\text{sub}(B) = B(i_b:i_b+n-1, j_b:j_b+nrhs-1)$  are *n*-by-*nrhs* distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor  $\text{sub}(A)$  as  $\text{sub}(A) = P * L * U$ , where  $P$  is a permutation matrix,  $L$  is unit lower triangular, and  $U$  is upper triangular.  $L$  and  $U$  are stored in  $\text{sub}(A)$ . The factored form of  $\text{sub}(A)$  is then used to solve the system of equations  $\text{sub}(A) * X = \text{sub}(B)$ .

**Input Parameters**

|                     |                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>            | (global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ( $n \geq 0$ ).                                         |
| <i>nrhs</i>         | (global) The number of right hand sides, that is, the number of columns of the distributed submatrices $B$ and $X$ ( $nrhs \geq 0$ ).                                              |
| <i>a</i> , <i>b</i> | (local)<br>Pointers into the local memory to arrays of local size $a: \text{lld}_a * \text{LOCc}(j_a + n - 1)$ and $b: \text{lld}_b * \text{LOCc}(j_b + nrhs - 1)$ , respectively. |

On entry, the array  $a$  contains the local pieces of the  $n$ -by- $n$  distributed matrix  $\text{sub}(A)$  to be factored.

On entry, the array  $b$  contains the right hand side distributed matrix  $\text{sub}(B)$ .

$ia, ja$

(global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of  $\text{sub}(A)$ , respectively.

$desca$

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

$ib, jb$

(global) The row and column indices in the global matrix  $B$  indicating the first row and the first column of  $\text{sub}(B)$ , respectively.

$descb$

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $B$ .

## Output Parameters

$a$

Overwritten by the factors  $L$  and  $U$  from the factorization  $\text{sub}(A) = P*L*U$ ; the unit diagonal elements of  $L$  are not stored .

$b$

Overwritten by the solution distributed matrix  $X$ .

$ipiv$

(local) Array of size  $LOCr(m\_a) + mb\_a$ . This array contains the pivoting information. The (local) row  $i$  of the matrix was interchanged with the (global) row  $ipiv[i - 1]$ .

This array is tied to the distributed matrix  $A$ .

$info$

(global) If  $info=0$ , the execution is successful.

$info < 0$ :

If the  $i$ -th argument is an array and the  $j$ -th entry had an illegal value, then  $info = -(i*100+j)$ ; if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

$info > 0$ :

If  $info = k$ ,  $U(ia+k-1,ja+k-1)$  is exactly zero. The factorization has been completed, but the factor  $U$  is exactly singular, so the solution could not be computed.

## Description

The `p?gesvx` function uses the *LU* factorization to compute the solution to a real or complex system of linear equations  $AX = B$ , where  $A$  denotes the  $n$ -by- $n$  submatrix  $A(ia:ia+n-1, ja:ja+n-1)$ ,  $B$  denotes the  $n$ -by- $nrhs$  submatrix  $B(ib:ib+n-1, jb:jb+nrhs-1)$  and  $X$  denotes the  $n$ -by- $nrhs$  submatrix  $X(ix:ix+n-1, jx:jx+nrhs-1)$ .

Error bounds on the solution and a condition estimate are also provided.

In the following description,  $af$  stands for the subarray of  $af$  from row  $iaf$  and column  $jaf$  to row  $iaf+n-1$  and column  $jaf+n-1$ .

The function `p?gesvx` performs the following steps:

1. If  $fact = 'E'$ , real scaling factors  $R$  and  $C$  are computed to equilibrate the system:

```

trans = 'N': diag(R)*A*diag(C) *diag(C)-1*X = diag(R)*B
trans = 'T': (diag(R)*A*diag(C))T *diag(R)-1*X = diag(C)*B
trans = 'C': (diag(R)*A*diag(C))H *diag(R)-1*X = diag(C)*B

```

Whether or not the system will be equilibrated depends on the scaling of the matrix  $A$ , but if equilibration is used,  $A$  is overwritten by `diag(R)*A*diag(C)` and  $B$  by `diag(R)*B` (if `trans='N'`) or `diag(C)*B` (if `trans = 'T' or 'C'`).

2. If  $fact = 'N'$  or  $'E'$ , the *LU* decomposition is used to factor the matrix  $A$  (after equilibration if  $fact = 'E'$ ) as  $A = PLU$ , where  $P$  is a permutation matrix,  $L$  is a unit lower triangular matrix, and  $U$  is upper triangular.
3. The factored form of  $A$  is used to estimate the condition number of the matrix  $A$ . If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.

4. The system of equations is solved for  $X$  using the factored form of  $A$ .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix  $X$  is premultiplied by  $\text{diag}(C)$  (if  $\text{trans} = \text{'N'}$ ) or  $\text{diag}(R)$  (if  $\text{trans} = \text{'T'}$  or  $\text{'C'}$ ) so that it solves the original system before equilibration.

## Input Parameters

*fact*

(global) Must be '`F`', '`N`', or '`E`'.

Specifies whether or not the factored form of the matrix  $A$  is supplied on entry, and if not, whether the matrix  $A$  should be equilibrated before it is factored.

If  $\text{fact} = \text{'F'}$  then, on entry,  $\text{af}$  and  $\text{ipiv}$  contain the factored form of  $A$ . If  $\text{equed}$  is not '`N`', the matrix  $A$  has been equilibrated with scaling factors given by  $r$  and  $c$ . Arrays  $a$ ,  $\text{af}$ , and  $\text{ipiv}$  are not modified.

If  $\text{fact} = \text{'N'}$ , the matrix  $A$  is copied to  $\text{af}$  and factored.

If  $\text{fact} = \text{'E'}$ , the matrix  $A$  is equilibrated if necessary, then copied to  $\text{af}$  and factored.

*trans*

(global) Must be '`N`', '`T`', or '`C`'.

Specifies the form of the system of equations:

If  $\text{trans} = \text{'N'}$ , the system has the form  $A*X = B$  (No transpose);

If  $\text{trans} = \text{'T'}$ , the system has the form  $A^T*X = B$  (Transpose);

If  $\text{trans} = \text{'C'}$ , the system has the form  $A^H*X = B$  (Conjugate transpose);

*n*

(global) The number of linear equations; the order of the submatrix  $A$  ( $n \geq 0$ ).

*nrhs*

(global) The number of right hand sides; the number of columns of the distributed submatrices  $B$  and  $X$  ( $nrhs \geq 0$ ).

*a, af, b, work*

(local)

Pointers into the local memory to arrays of local size  $a: \text{lld\_a*LOCc}(ja+n-1)$ ,  $\text{af}: \text{lld\_af*LOCc}(ja+n-1)$ ,  $b: \text{lld\_b*LOCc}(jb+nrhs-1)$ ,  $\text{work}: \text{lwork}$ .

The array  $a$  contains the matrix  $A$ . If  $\text{fact} = \text{'F'}$  and  $\text{equed}$  is not '`N`', then  $A$  must have been equilibrated by the scaling factors in  $r$  and/or  $c$ .

The array  $\text{af}$  is an input argument if  $\text{fact} = \text{'F'}$ . In this case it contains on entry the factored form of the matrix  $A$ , that is, the factors  $L$  and  $U$  from the factorization  $A = P*L*U$  as computed by [p?getrf](#). If  $\text{equed}$  is not '`N`', then  $\text{af}$  is the factored form of the equilibrated matrix  $A$ .

The array  $b$  contains on entry the matrix  $B$  whose columns are the right-hand sides for the systems of equations.

$\text{work}$  is a workspace array. The size of  $\text{work}$  is ( $\text{lwork}$ ).

*ia, ja*

(global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A(ia:ia+n-1, ja:ja+n-1)$ , respectively.

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <i>desca</i>    | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>iaf, jaf</i> | (global) The row and column indices in the global matrix <i>AF</i> indicating the first row and the first column of the subarray <i>af</i> , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>descacf</i>  | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>AF</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>ib, jb</i>   | (global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B(ib:ib+n-1, jb:jb+nrhs-1)</i> , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>descb</i>    | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>ipiv</i>     | (local) Array of size <i>LOCr(m_a)+mb_a</i> .<br>The array <i>ipiv</i> is an input argument if <i>fact = 'F'</i> .<br>On entry, it contains the pivot indices from the factorization $A = P^*L^*U$ as computed by <i>p?getrf</i> ; (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv[i - 1]</i> .<br>This array must be aligned with <i>A(ia:ia+n-1, *)</i> .<br><br>If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact = 'N'</i> );<br>If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag(r)</i> ;<br>If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag(c)</i> ;<br>If <i>equed</i> = 'B', both row and column equilibration was done; <i>A</i> has been replaced by <i>diag(r)*A*diag(c)</i> .<br><br>(local)<br>Arrays of size <i>LOCr(m_a)</i> and <i>LOCc(n_a)</i> , respectively.<br>The array <i>r</i> contains the row scale factors for <i>A</i> , and the array <i>c</i> contains the column scale factors for <i>A</i> . These arrays are input arguments if <i>fact = 'F'</i> only; otherwise they are output arguments. If <i>equed = 'R' or 'B'</i> , <i>A</i> is multiplied on the left by <i>diag(r)</i> ; if <i>equed = 'N' or 'C'</i> , <i>r</i> is not accessed.<br>If <i>fact = 'F'</i> and <i>equed = 'R' or 'B'</i> , each element of <i>r</i> must be positive.<br>If <i>equed = 'C' or 'B'</i> , <i>A</i> is multiplied on the right by <i>diag(c)</i> ; if <i>equed = 'N' or 'R'</i> , <i>c</i> is not accessed.<br>If <i>fact = 'F'</i> and <i>equed = 'C' or 'B'</i> , each element of <i>c</i> must be positive. Array <i>r</i> is replicated in every process column, and is aligned with the distributed matrix <i>A</i> . Array <i>c</i> is replicated in every process row, and is aligned with the distributed matrix <i>A</i> . |

|               |                                                                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ix, jx</i> | (global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$ , respectively.                                                                  |
| <i>descx</i>  | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $X$ .                                                                                                                                     |
| <i>lwork</i>  | (local or global) The size of the array <i>work</i> ; must be at least $\max(p?gecon(lwork), p?gerfs(lwork)) + LOCr(n_a)$ .                                                                                                               |
| <i>iwork</i>  | (local, <i>pgesvx/pdgesvx</i> only). Workspace array. The size of <i>iwork</i> is ( <i>liwork</i> ).                                                                                                                                      |
| <i>liwork</i> | (local, <i>pgesvx/pdgesvx</i> only). The size of the array <i>iwork</i> , must be at least <i>LOCr(n_a)</i> .                                                                                                                             |
| <i>rwork</i>  | (local)<br>Workspace array, used in complex flavors only.<br>The size of <i>rwork</i> is ( <i>lrwork</i> ).<br><br>(local or global, <i>pcgesvx/pzgesvx</i> only). The size of the array <i>rwork</i> ;must be at least $2 * LOCc(n_a)$ . |

## Output Parameters

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

See the description of  $r$ ,  $c$  in *Input Arguments* section.

$rcond$

(global).

An estimate of the reciprocal condition number of the matrix  $A$  after equilibration (if done). The function sets  $rcond = 0$  if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime  $rcond$  is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

$ferr$ ,  $berr$

(local)

Arrays of size  $\text{LOCc}(\text{n\_b})$  each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

Arrays  $ferr$  and  $berr$  are both replicated in every process row, and are aligned with the matrices  $B$  and  $X$ .

$ipiv$

If  $\text{fact} = \text{'N'}$  or  $\text{'E'}$ , then  $ipiv$  is an output argument and on exit contains the pivot indices from the factorization  $A = P \cdot L \cdot U$  of the original matrix  $A$  (if  $\text{fact} = \text{'N'}$ ) or of the equilibrated matrix  $A$  (if  $\text{fact} = \text{'E'}$ ).

$equed$

If  $\text{fact} \neq \text{'F'}$ , then  $equed$  is an output argument. It specifies the form of equilibration that was done (see the description of  $equed$  in *Input Arguments* section).

$work[0]$

If  $\text{info}=0$ , on exit  $work[0]$  returns the minimum value of  $lwork$  required for optimum performance.

$iwork[0]$

If  $\text{info}=0$ , on exit  $iwork[0]$  returns the minimum value of  $liwork$  required for optimum performance.

$rwork[0]$

If  $\text{info}=0$ , on exit  $rwork[0]$  returns the minimum value of  $lrwork$  required for optimum performance.

$info$

If  $\text{info}=0$ , the execution is successful.

$\text{info} < 0$ : if the  $i$ th argument is an array and the  $j$ th entry had an illegal value, then  $\text{info} = -(i*100+j)$ ; if the  $i$ th argument is a scalar and had an illegal value, then  $\text{info} = -i$ . If  $\text{info} = i$ , and  $i \leq n$ , then  $U(i,i)$  is exactly zero. The factorization has been completed, but the factor  $U$  is exactly singular, so the solution and error bounds could not be computed. If  $\text{info} = i$ , and  $i = n + 1$ , then  $U$  is nonsingular, but  $rcond$  is less than machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed.

## Description

The `p?gbsv` function computes the solution to a real or complex system of linear equations

`sub(A)*X = sub(B)`,

where `sub(A) = A(1:n, ja:ja+n-1)` is an  $n$ -by- $n$  real/complex general banded distributed matrix with  $bwl$  subdiagonals and  $bwu$  superdiagonals, and  $X$  and `sub(B) = B(ib:ib+n-1, 1:rhs)` are  $n$ -by- $nrhs$  distributed matrices.

The  $LU$  decomposition with partial pivoting and row interchanges is used to factor `sub(A)` as `sub(A) = P*L*U*Q`, where  $P$  and  $Q$  are permutation matrices, and  $L$  and  $U$  are banded lower and upper triangular matrices, respectively. The matrix  $Q$  represents reordering of columns for the sake of parallelism, while  $P$  represents reordering of rows for numerical stability using classic partial pivoting.

## Input Parameters

|                   |                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>    | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix <code>sub(A)</code> ( $n \geq 0$ ). |
| <code>bwl</code>  | (global) The number of subdiagonals within the band of $A$ ( $0 \leq bwl \leq n-1$ ).                                                       |
| <code>bwu</code>  | (global) The number of superdiagonals within the band of $A$ ( $0 \leq bwu \leq n-1$ ).                                                     |
| <code>nrhs</code> | (global) The number of right hand sides; the number of columns of the distributed matrix <code>sub(B)</code> ( $nrhs \geq 0$ ).             |
| <code>a, b</code> | (local)<br>Pointers into the local memory to arrays of local size $a: lld\_a * LOCc(ja + n - 1)$ and $b: lld\_b * LOCc(nrhs)$ .             |

On entry, the array  $a$  contains the local pieces of the global array  $A$ .

On entry, the array  $b$  contains the right hand side distributed matrix sub( $B$ ).

$ja$

(global) The index in the global matrix  $A$  indicating the start of the matrix to be operated on (which may be either all of  $A$  or a submatrix of  $A$ ).

$desca$

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

If  $desca[dtype_-1] = 501$ , then  $dlen_ \geq 7$ ;

else if  $desca[dtype_-1] = 1$ , then  $dlen_ \geq 9$ .

$ib$

(global) The row index in the global matrix  $B$  indicating the first row of the matrix to be operated on (which may be either all of  $B$  or a submatrix of  $B$ ).

$descb$

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $B$ .

If  $descb[dtype_-1] = 502$ , then  $dlen_ \geq 7$ ;

else if  $descb[dtype_-1] = 1$ , then  $dlen_ \geq 9$ .

$work$

(local)

Workspace array of size  $lwork$ .

$lwork$

(local or global) The size of the array  $work$ , must be at least  $lwork \geq (NB + bwu) * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu) + max(nrhs * (NB + 2 * bwl + 4 * bwu), 1)$ .

## Output Parameters

$a$

On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

$b$

On exit, this array contains the local pieces of the solution distributed matrix  $X$ .

$ipiv$

(local) array.

The size of  $ipiv$  must be at least  $desca[NB - 1]$ . This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.

$work[0]$

On exit,  $work[0]$  contains the minimum value of  $lwork$  required for optimum performance.

$info$

If  $info=0$ , the execution is successful.  $info < 0$ :

If the  $i$ -th argument is an array and the  $j$ -th entry had an illegal value, then  $info = -(i * 100 + j)$ ; if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

$info > 0$ :

If  $info = k \leq \text{NPROCS}$ , the submatrix stored on processor  $info$  and factored locally was not nonsingular, and the factorization was not completed. If  $info = k > \text{NPROCS}$ , the submatrix stored on processor  $info-\text{NPROCS}$  representing interactions with other processors was not nonsingular, and the factorization was not completed.

## Description

The p?dbsvfunction solves the following system of linear equations:

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where  $A(1:n, ja:ja+n-1)$  is an  $n$ -by- $n$  real/complex banded diagonally dominant-like distributed matrix with bandwidth  $bwl$ ,  $bwu$ .

Gaussian elimination without pivoting is used to factor a reordering of the matrix into  $LU$ .

## Description

The function solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where *A*(1:*n*, *ja*:*ja*+*n*-1) is an *n*-by-*n* complex tridiagonal diagonally dominant-like distributed matrix.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into *L U*.

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

## Description

The `p?posv` function computes the solution to a real/complex system of linear equations

`sub(A) *X = sub(B),`

where `sub(A)` denotes  $A(ia:ia+n-1, ja:ja+n-1)$  and is an  $n$ -by- $n$  symmetric/Hermitian distributed positive definite matrix and  $X$  and `sub(B)` denoting  $B(ib:ib+n-1, jb:jb+nrhs-1)$  are  $n$ -by- $nrhs$  distributed matrices. The Cholesky decomposition is used to factor `sub(A)` as

`sub(A) = U^T * U, if uplo = 'U', or`

`sub(A) = L * L^T, if uplo = 'L',`

where  $U$  is an upper triangular matrix and  $L$  is a lower triangular matrix. The factored form of `sub(A)` is then used to solve the system of equations.

## Input Parameters

`uplo`

(global) Must be '`U`' or '`L`'.

Indicates whether the upper or lower triangular part of `sub(A)` is stored.

`n`

(global) The order of the distributed matrix `sub(A)` ( $n \geq 0$ ).

`nrhs`

The number of right-hand sides; the number of columns of the distributed matrix `sub(B)` ( $nrhs \geq 0$ ).

`a`

(local)

Pointer into the local memory to an array of size  $lld\_a * LOCc(ja+n-1)$ . On entry, this array contains the local pieces of the  $n$ -by- $n$  symmetric distributed matrix `sub(A)` to be factored.

If `uplo = 'U'`, the leading  $n$ -by- $n$  upper triangular part of `sub(A)` contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If `uplo = 'L'`, the leading  $n$ -by- $n$  lower triangular part of `sub(A)` contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.

`ia, ja`

(global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A$ , respectively.

`desca`

(global and local) array of size `dlen_`. The array descriptor for the distributed matrix  $A$ .

`b`

(local)

Pointer into the local memory to an array of size  $lld\_b * LOCc(jb+nrhs-1)$ . On entry, the local pieces of the right hand sides distributed matrix `sub(B)`.

`ib, jb`

(global) The row and column indices in the global matrix  $B$  indicating the first row and the first column of the submatrix  $B$ , respectively.

`descb`

(global and local) array of size `dlen_`. The array descriptor for the distributed matrix  $B$ .

## Output Parameters

- a* On exit, if *info* = 0, this array contains the local pieces of the factor *U* or *L* from the Cholesky factorization  $\text{sub}(A) = U^H \star U$ , or  $L \star L^H$ .
- b* On exit, if *info* = 0,  $\text{sub}(B)$  is overwritten by the solution distributed matrix *X*.
- info* (global)  
If *info* = 0, the execution is successful.  
If *info* < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = -(*i*\*100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.  
If *info* > 0: If *info* = *k*, the leading minor of order *k*,  $A(ia:ia+k-1, ja:ja+k-1)$  is not positive definite, and the factorization could not be completed, and the solution has not been computed.

## Description

The `p?posvx` function uses the Cholesky factorization  $A=U^T \cdot U$  or  $A=L \cdot L^T$  to compute the solution to a real or complex system of linear equations

$$A(ia:ia+n-1, ja:ja+n-1) \cdot X = B(ib:ib+n-1, jb:jb+nrhs-1),$$

where  $A(ia:ia+n-1, ja:ja+n-1)$  is a  $n$ -by- $n$  matrix and  $X$  and  $B(ib:ib+n-1, jb:jb+nrhs-1)$  are  $n$ -by- $nrhs$  matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments  $y$  denotes  $Y(iy:iy+m-1, jy:jy+k-1)$ , an  $m$ -by- $k$  matrix where  $y$  can be  $a$ ,  $af$ ,  $b$  and  $x$ .

The function `p?posvx` performs the following steps:

1. If  $fact = 'E'$ , real scaling factors  $s$  are computed to equilibrate the system:

$$\text{diag}(sr) \cdot A \cdot \text{diag}(sc) \cdot \text{inv}(\text{diag}(sc)) \cdot X = \text{diag}(sr) \cdot B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix  $A$ , but if equilibration is used,  $A$  is overwritten by  $\text{diag}(sr) \cdot A \cdot \text{diag}(sc)$  and  $B$  by  $\text{diag}(sr) \cdot B$ .

2. If  $fact = 'N'$  or  $'E'$ , the Cholesky decomposition is used to factor the matrix  $A$  (after equilibration if  $fact = 'E'$ ) as

$$A = U^T \cdot U, \text{ if } uplo = 'U', \text{ or}$$

$$A = L \cdot L^T, \text{ if } uplo = 'L',$$

where  $U$  is an upper triangular matrix and  $L$  is a lower triangular matrix.

3. The factored form of  $A$  is used to estimate the condition number of the matrix  $A$ . If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped

4. The system of equations is solved for  $X$  using the factored form of  $A$ .

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix  $X$  is premultiplied by  $\text{diag}(sr)$  so that it solves the original system before equilibration.

## Input Parameters

`fact`

(global) Must be '`F`', '`N`', or '`E`'.

Specifies whether or not the factored form of the matrix  $A$  is supplied on entry, and if not, whether the matrix  $A$  should be equilibrated before it is factored.

If  $fact = 'F'$ : on entry,  $af$  contains the factored form of  $A$ . If  $equed = 'Y'$ , the matrix  $A$  has been equilibrated with scaling factors given by  $s$ .  $a$  and  $af$  will not be modified.

If  $fact = 'N'$ , the matrix  $A$  will be copied to  $af$  and factored.

If  $fact = 'E'$ , the matrix  $A$  will be equilibrated if necessary, then copied to  $af$  and factored.

`uplo`

(global) Must be '`U`' or '`L`'.

Indicates whether the upper or lower triangular part of  $A$  is stored.

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <i>equed</i>    | (global) Must be ' $N$ ' or ' $Y$ '.<br><br>$equed$ is an input argument if $fact = 'F'$ . It specifies the form of equilibration that was done:<br><br>If $equed = 'N'$ , no equilibration was done (always true if $fact = 'N'$ );<br>If $equed = 'Y'$ , equilibration was done and $A$ has been replaced by $\text{diag}(sr) * A * \text{diag}(sc)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>sr</i>       | (local)<br><br>Array of size $lld\_a$ .<br><br>The array $s$ contains the scale factors for $A$ . This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.<br><br>If $equed = 'N'$ , $s$ is not accessed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

If  $\text{fact} = \text{'F'}$  and  $\text{equed} = \text{'Y'}$ , each element of  $s$  must be positive.

*b*

(local)

Pointer into the local memory to an array of local size  $\text{lld}_b * \text{LOCc}(jb + nrhs - 1)$ . On entry, the  $n$ -by- $nrhs$  right-hand side matrix  $B$ .

*ib, jb*

(global) The row and column indices in the global matrix  $B$  indicating the first row and the first column of the submatrix  $B$ , respectively.

*descb*

(global and local) Array of size  $dlen_$ . The array descriptor for the distributed matrix  $B$ .

*x*

(local)

Pointer into the local memory to an array of local size  $\text{lld}_x * \text{LOCc}(jx + nrhs - 1)$ .

*ix, jx*

(global) The row and column indices in the global matrix  $X$  indicating the first row and the first column of the submatrix  $X$ , respectively.

*descx*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $X$ .

*work*

(local)

Workspace array of size  $lwork$ .

*lwork*

(local or global)

The size of the array  $work$ .  $lwork$  is local input and must be at least  $lwork = \max(p?pocon(lwork), p?porfs(lwork)) + \text{LOCr}(n\_a)$ .

$lwork = 3 * \text{descb}[lld\_ - 1]$ .

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

*iwork*(local) Workspace array of size  $liwork$ .*liwork*

(local or global)

The size of the array  $iwork$ .  $liwork$  is local input and must be at least  $liwork = \text{descb}[lld\_ - 1] liwork = \text{LOCr}(n\_a)$ .

If  $liwork = -1$ , then  $liwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

## Output Parameters

*a*

On exit, if  $\text{fact} = \text{'E'}$  and  $\text{equed} = \text{'Y'}$ ,  $a$  is overwritten by  $\text{diag}(sr) * a * \text{diag}(sc)$ .

*af*

If  $\text{fact} = \text{'N'}$ , then  $af$  is an output argument and on exit returns the triangular factor  $U$  or  $L$  from the Cholesky factorization  $A = U^T * U$  or  $A = L * L^T$  of the original matrix  $A$ .

If  $\text{fact} = \text{'E'}$ , then  $\text{af}$  is an output argument and on exit returns the triangular factor  $U$  or  $L$  from the Cholesky factorization  $A = U^T * U$  or  $A = L * L^T$  of the equilibrated matrix  $A$  (see the description of  $A$  for the form of the equilibrated matrix).

*equed*  
If  $\text{fact} \neq \text{'F'}$ , then  $\text{equed}$  is an output argument. It specifies the form of equilibration that was done (see the description of  $\text{equed}$  in *Input Arguments* section).

*sr*  
This array is an output argument if  $\text{fact} \neq \text{'F'}$ .

See the description of  $\text{sr}$  in *Input Arguments* section.

*sc*  
This array is an output argument if  $\text{fact} \neq \text{'F'}$ .

See the description of  $\text{sc}$  in *Input Arguments* section.

*b*  
On exit, if  $\text{equed} = \text{'N'}$ ,  $\text{b}$  is not modified; if  $\text{trans} = \text{'N'}$  and  $\text{equed} = \text{'R'}$  or  $\text{'B'}$ ,  $\text{b}$  is overwritten by  $\text{diag}(\text{r}) * \text{b}$ ; if  $\text{trans} = \text{'T'}$  or  $\text{'C'}$  and  $\text{equed} = \text{'C'}$  or  $\text{'B'}$ ,  $\text{b}$  is overwritten by  $\text{diag}(\text{c}) * \text{b}$ .

*x*  
(local)

If  $\text{info} = 0$  the  $n$ -by- $nrhs$  solution matrix  $X$  to the original system of equations.

Note that  $A$  and  $B$  are modified on exit if  $\text{equed} \neq \text{'N'}$ , and the solution to the equilibrated system is

$\text{inv}(\text{diag}(\text{sc})) * X$  if  $\text{trans} = \text{'N'}$  and  $\text{equed} = \text{'C'}$  or  $\text{'B'}$ , or  
 $\text{inv}(\text{diag}(\text{sr})) * X$  if  $\text{trans} = \text{'T'}$  or  $\text{'C'}$  and  $\text{equed} = \text{'R'}$  or  $\text{'B'}$ .

*rcond*  
(global)

An estimate of the reciprocal condition number of the matrix  $A$  after equilibration (if done). If  $\text{rcond}$  is less than the machine precision (in particular, if  $\text{rcond}=0$ ), the matrix is singular to working precision. This condition is indicated by a return code of  $\text{info} > 0$ .

*ferr*  
Arrays of size at least  $\max(LOC, n\_b)$ . The estimated forward error bounds for each solution vector  $X(j)$  (the  $j$ -th column of the solution matrix  $X$ ). If  $xtrue$  is the true solution,  $\text{ferr}[j - 1]$  bounds the magnitude of the largest entry in  $(X(j) - xtrue)$  divided by the magnitude of the largest entry in  $X(j)$ . The quality of the error bound depends on the quality of the estimate of  $\text{norm}(\text{inv}(A))$  computed in the code; if the estimate of  $\text{norm}(\text{inv}(A))$  is accurate, the error bound is guaranteed.

*berr*  
(local)

Arrays of size at least  $\max(LOC, n\_b)$ . The componentwise relative backward error of each solution vector  $X(j)$  (the smallest relative change in any entry of  $A$  or  $B$  that makes  $X(j)$  an exact solution).

*work[0]*  
(local) On exit,  $\text{work}[0]$  returns the minimal and optimal  $lwork$ .

*info*  
(global)

If  $\text{info}=0$ , the execution is successful.

$< 0$ : if  $\text{info} = -i$ , the  $i$ -th argument had an illegal value

$> 0$ : if  $\text{info} = i$ , and  $i$  is  $\leq n$ : if  $\text{info} = i$ , the leading minor of order  $i$  of  $a$  is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.

$= n+1$ :  $rcond$  is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

## Description

The p?pbsv function solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where  $A(1:n, ja:ja+n-1)$  is an  $n$ -by- $n$  real/complex banded symmetric positive definite distributed matrix with bandwidth  $bw$ .

Cholesky factorization is used to factor a reordering of the matrix into  $L*L'$ .

## Input Parameters

*uplo* (global) Must be 'U' or 'L'.

Indicates whether the upper or lower triangular of  $A$  is stored.

|         |                                                                                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         | If $uplo = 'U'$ , the upper triangular $A$ is stored<br>If $uplo = 'L'$ , the lower triangular of $A$ is stored.                                                                                                                                             |
| $n$     | (global) The order of the distributed matrix $A$ ( $n \geq 0$ ).                                                                                                                                                                                             |
| $bw$    | (global) The number of subdiagonals in $L$ or $U$ . $0 \leq bw \leq n-1$ .                                                                                                                                                                                   |
| $nrhs$  | (global) The number of right-hand sides; the number of columns in $B$ ( $nrhs \geq 0$ ).                                                                                                                                                                     |
| $a$     | (local).<br>Pointer into the local memory to an array with leading size $lld_a \geq (bw + 1)$ (stored in $desca$ ). On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.                                 |
| $ja$    | (global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).                                                                                                    |
| $desca$ | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .                                                                                                                                                             |
| $b$     | (local)<br>Pointer into the local memory to an array of local lead size $lld_b \geq nb$ . On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$ .                                                                    |
| $ib$    | (global) The row index in the global matrix $B$ indicating the first row of the matrix to be operated on (which may be either all of $b$ or a submatrix of $B$ ).                                                                                            |
| $descb$ | (global and local) array of size $dlen_$ .<br>If 1D type ( $dtype_b = 502$ ), $dlen \geq 7$ ;<br>If 2D type ( $dtype_b = 1$ ), $dlen \geq 9$ .<br>The array descriptor for the distributed matrix $B$ .<br>Contains information of mapping of $B$ to memory. |
| $work$  | (local).<br>Temporary workspace. This space may be overwritten in between calls to functions. $work$ must be the size given in $lwork$ .                                                                                                                     |
| $lwork$ | (local or global) Size of user-input workspace $work$ . If $lwork$ is too small, the minimal acceptable size will be returned in $work[0]$ and an error code is returned. $lwork \geq (nb+2*bw)*bw + \max((bw*nrhs), bw*bw)$                                 |

## Output Parameters

|        |                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $a$    | On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK. |
| $b$    | On exit, contains the local piece of the solutions distributed matrix $X$ .                                                                                                                                     |
| $work$ | On exit, $work[0]$ contains the minimal $lwork$ .                                                                                                                                                               |
| $info$ | (global) If $info=0$ , the execution is successful.                                                                                                                                                             |

< 0: If the  $i$ -th argument is an array and the  $j$ -entry had an illegal value, then  $\text{info} = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $\text{info} = -i$ .

> 0: If  $\text{info} = k \leq \text{NPROCS}$ , the submatrix stored on processor  $\text{info}$  and factored locally was not positive definite, and the factorization was not completed.

If  $\text{info} = k > \text{NPROCS}$ , the submatrix stored on processor  $\text{info-NPROCS}$  representing interactions with other processors was not positive definite, and the factorization was not completed.

## Description

The p?gels function solves overdetermined or underdetermined real/ complex linear systems involving an *m*-by-*n* matrix *sub(A)* = *A*(*ia*:*ia+m-1*,*ja*:*ja+n-1*), or its transpose/ conjugate-transpose, using a *QTQ* or *LQ* factorization of *sub(A)*. It is assumed that *sub(A)* has full rank.

The following options are provided:

1. If *trans* = 'N' and *m*≥*n*: find the least squares solution of an overdetermined system, that is, solve the least squares problem

- minimize  $\| \text{sub}(B) - \text{sub}(A)^*X \|$
- 2.** If  $\text{trans} = 'N'$  and  $m < n$ : find the minimum norm solution of an underdetermined system  $\text{sub}(A)^*X = \text{sub}(B)$ .
  - 3.** If  $\text{trans} = 'T'$  and  $m \geq n$ : find the minimum norm solution of an undetermined system  $\text{sub}(A)^T X = \text{sub}(B)$ .
  - 4.** If  $\text{trans} = 'T'$  and  $m < n$ : find the least squares solution of an overdetermined system, that is, solve the least squares problem

minimize  $\| \text{sub}(B) - \text{sub}(A)^T X \|$ ,

where  $\text{sub}(B)$  denotes  $B(ib:ib+m-1, jb:jb+nrhs-1)$  when  $\text{trans} = 'N'$  and  $B(ib:ib+n-1, jb:jb+nrhs-1)$  otherwise. Several right hand side vectors  $b$  and solution vectors  $x$  can be handled in a single call; when  $\text{trans} = 'N'$ , the solution vectors are stored as the columns of the  $n$ -by- $nrhs$  right hand side matrix  $\text{sub}(B)$  and the  $m$ -by- $nrhs$  right hand side matrix  $\text{sub}(B)$  otherwise.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
mpb0 = numroc(m+iroffb, mb_b, MYROW, icrow, NPROW),
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol, NPCOL),

```

---

**NOTE**

*mod(x,y)* is the integer remainder of *x/y*.

---

*ilcm*, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW*, and *NPCOL* can be determined by calling the function *blacs\_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

## Output Parameters

- a*
- On exit, If  $m \geq n$ ,  $\text{sub}(A)$  is overwritten by the details of its QR factorization as returned by [p?geqrf](#); if  $m < n$ ,  $\text{sub}(A)$  is overwritten by details of its LQ factorization as returned by [p?gelqf](#).
- b*
- On exit,  $\text{sub}(B)$  is overwritten by the solution vectors, stored columnwise: if  $\text{trans} = 'N'$  and  $m \geq n$ , rows 1 to  $n$  of  $\text{sub}(B)$  contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements  $n+1$  to  $m$  in that column;
- If  $\text{trans} = 'N'$  and  $m < n$ , rows 1 to  $n$  of  $\text{sub}(B)$  contain the minimum norm solution vectors;
- If  $\text{trans} = 'T'$  and  $m \geq n$ , rows 1 to  $m$  of  $\text{sub}(B)$  contain the minimum norm solution vectors; if  $\text{trans} = 'T'$  and  $m < n$ , rows 1 to  $m$  of  $\text{sub}(B)$  contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements  $m+1$  to  $n$  in that column.
- work[0]*
- On exit,  $\text{work}[0]$  contains the minimum value of  $\text{lwork}$  required for optimum performance.
- info*
- (global)
- = 0: the execution is successful.
- < 0: if the  $i$ -th argument is an array and the  $j$ -entry had an illegal value, then  $\text{info} = - (i * 100 + j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $\text{info} = -i$ .

### Description

The `p?syev` function computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix  $A$  by calling the recommended sequence of ScaLAPACK functions.

In its present form, the function assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

## Input Parameters

*np* = the number of rows local to a given process.

*nq* = the number of columns local to a given process.

*jobz* (global) Must be '*N*' or '*V*'. Specifies if it is necessary to compute the eigenvectors:

If *jobz* ='*N*', then only eigenvalues are computed.

If *jobz* ='*V*', then eigenvalues and eigenvectors are computed.

*uplo* (global) Must be '*U*' or '*L*'. Specifies whether the upper or lower triangular part of the symmetric matrix *A* is stored:

If *uplo* = '*U*', *a* stores the upper triangular part of *A*.

If *uplo* = '*L*', *a* stores the lower triangular part of *A*.

*n* (global) The number of rows and columns of the matrix *A* ( $n \geq 0$ ).

*a* (local)

Block cyclic array of global size  $n*n$  and local size  $lld\_a*LOCc(ja+n-1)$ . On entry, the symmetric matrix *A*.

If *uplo* = '*U*', only the upper triangular part of *A* is used to define the elements of the symmetric matrix.

If *uplo* = '*L*', only the lower triangular part of *A* is used to define the elements of the symmetric matrix.

*ia, ja* (global) The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

*desca* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

*iz, jz* (global) The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

*descz* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *Z*.

*work* (local)

Array of size *lwork*.

*lwork* (local) See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = '*N*'), then  $lwork \geq 5*n + sizesytrd + 1$ ,

where *sizesytrd* is the workspace for *p?sytrd* and is  $\max(NB*(np + 1), 3*NB)$ .

If eigenvectors are requested (*jobz* = '*V*') then the amount of workspace required to guarantee that all eigenvectors are computed is:

*qrmem* =  $2*n-2$

```
lwmin = 5*n + n*ldc + max(sizemqrleft, qrmem) + 1
```

Variable definitions:

```
nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] =
descz[nb_ - 1];
nn = max(n, nb, 2);
desca[rsrc_ - 1] = desca[rsrc_ - 1] = descz[rsrc_ - 1] =
descz[csrc_ - 1] = 0
np = numroc(nn, nb, 0, 0, NPROW)
nq = numroc(max(n, nb, 2), nb, 0, 0, NPCOL)
nrc = numroc(n, nb, myprowc, 0, NPROCS)
ldc = max(1, nrc)
```

*sizemqrleft* is the workspace for *p?ormtr* when its *side* argument is 'L'.

*myprowc* is defined when a new context is created as follows:

```
call blacs_get(desca[ctxt_ - 1], 0, contextc)
call blacs_gridinit(contextc, 'R', NPROCS, 1)
call blacs_gridinfo(contextc, nprowc, npcolc, myprowc,
mypcolc)
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

## Output Parameters

*a*

On exit, the lower triangle (if *uplo*='L') or the upper triangle (if *uplo*='U') of *A*, including the diagonal, is destroyed.

*w*

(global).

Array of size *n*.

On normal exit, the first entries contain the selected eigenvalues in ascending order.

*z*

(local).

Array, global size *n*\**n*, local size *lld\_z*\**LOCc(jz+n-1)*. If *jobz* = 'V', then on normal exit the first columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues.

If *jobz* = 'N', then *z* is not referenced.

*work[0]*

On output, *work[0]* returns the workspace needed to guarantee completion. If the input parameters are incorrect, *work[0]* may also be incorrect.

If *jobz* = 'N' *work[0]* = minimal (optimal) amount of workspace

If *jobz* = 'V' *work[0]* = minimal workspace required to generate all the eigenvectors.

*info* (global)

If *info* = 0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i*\*100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0:

If *info*= 1 through *n*, the *i*-th eigenvalue did not converge in ?steqr2 after a total of  $30n$  iterations.

If *info*= *n*+1, then p?syev has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?syev cannot be guaranteed.

## Description

The p?syevd function computes all eigenvalues and eigenvectors of a real symmetric matrix *A* by using a divide and conquer algorithm.

## Input Parameters

*np* = the number of rows local to a given process.

*nq* = the number of columns local to a given process.

*jobz* (global) Must be 'N' or 'V'.

Specifies whether it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed (**not yet implemented**).

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Description

`p?syevr` computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix  $A$  distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix  $A$  is reduced to real symmetric tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in  $w$ . The eigenvector matrix  $z$  is stored in 2D block-cyclic format distributed over all processors.

Note that subsets of eigenvalues/vectors can be selected by specifying a range of values or a range of indices for the desired eigenvalues.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

|                    | = 'V': all eigenvalues in the interval $[v_l, v_u]$ will be found.                                                                                                                                                                                                                                                                 |
|                    | = 'I': the $i_l$ -th through $i_u$ -th eigenvalues will be found.                                                                                                                                                                                                                                                                  |
| <code>uplo</code>  | (global)                                                                                                                                                                                                                                                                                                                           |
|                    | Specifies whether the upper or lower triangular part of the symmetric matrix $A$ is stored:                                                                                                                                                                                                                                        |
|                    | = 'U': Upper triangular                                                                                                                                                                                                                                                                                                            |
|                    | = 'L': Lower triangular                                                                                                                                                                                                                                                                                                            |
| <code>n</code>     | (global )                                                                                                                                                                                                                                                                                                                          |
|                    | The number of rows and columns of the matrix $a$ . $n \geq 0$                                                                                                                                                                                                                                                                      |
| <code>a</code>     | Block cyclic array of global size $n * n$ , local size $l/d_a * LOC_c(j_a + n - 1)$ .                                                                                                                                                                                                                                              |
|                    | This array contains the local pieces of the symmetric distributed matrix $A$ . If <code>uplo</code> = 'U', only the upper triangular part of $a$ is used to define the elements of the symmetric matrix. If <code>uplo</code> = 'L', only the lower triangular part of $a$ is used to define the elements of the symmetric matrix. |
|                    | On exit, the lower triangle (if <code>uplo</code> ='L') or the upper triangle (if <code>uplo</code> ='U') of $a$ , including the diagonal, is destroyed.                                                                                                                                                                           |

*ia*

(global )

Global row index in the global matrix *A* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

*ja*

(global )

Global column index in the global matrix *A* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

*descA*(global and local) array of size *dlen\_*=9.

The array descriptor for the distributed matrix *a*.

*vl*

(global )

If *range*='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

*vu*

(global )

If *range*='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

*il*

(global )

If *range*='I', the index (from smallest to largest) of the smallest eigenvalue to be returned.  $il \geq 1$ .

Not referenced if *range* = 'A'.

*iu*

(global )

If *range*='I', the index (from smallest to largest) of the largest eigenvalue to be returned.  $\min(il,n) \leq iu \leq n$ .

Not referenced if *range* = 'A'.

*iz*

(global )

Global row index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

*zj*

(global )

Global column index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

*descZ*array of size *dlen\_*.

The array descriptor for the distributed matrix *z*.

The context *descZ*[*ctxt\_* - 1] must equal *descA*[*ctxt\_* - 1]. Also note the array alignment requirements specified below.

*work*(local workspace) array of size *lwork**lwork*

(local )

Size of *work*, must be at least 3.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N') then

$$lwork \geq 2 + 5*n + \max( 12 * nn, neig * ( np0 + 1 ) )$$

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

$$lwork \geq 2 + 5*n + \max( 18*nn, np0 * mq0 + 2 * neig * neig ) + (2 + \text{ceil}( neig, nprow * ncol )) * nn$$

Variable definitions:

*neig* = number of eigenvectors requested

$$nb = \text{desca}[ mb\_ - 1 ] = \text{desca}( nb\_ ) = \text{descz}[ mb\_ - 1 ] = \text{descz}( nb\_ )$$

$$nn = \max( n, neig, 2 )$$

$$\text{desca}[ rsrc\_ - 1 ] = \text{desca}[ csrc\_nb\_ - 1 ] = \text{descz}[ rsrc\_ - 1 ] = \text{descz}[ csrc\_ - 1 ] = 0$$

$$np0 = \text{numroc}( nn, neig, 0, 0, nprow )$$

$$mq0 = \text{numroc}( \max( neig, neig, 2 ), neig, 0, 0, ncol )$$

*ceil*( *x*, *y* ) is a ScaLAPACK function returning ceiling(*x/y*), and *nprow* and *ncol* can be determined by calling the function *blacs\_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pixerbla*.

*liwork*

(local)

size of *iwork*

Let *nnp* =  $\max( n, nprow * ncol + 1, 4 )$ . Then:

$$liwork \geq 12 * nnp + 2 * n \text{ when the eigenvectors are desired}$$

$$liwork \geq 10 * nnp + 2 * n \text{ when only the eigenvalues have to be computed}$$

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pixerbla*.

## OUTPUT Parameters

*m*

(global)

Total number of eigenvalues found.  $0 \leq m \leq n$ .

*nz*

(global)

Total number of eigenvectors computed.  $0 \leq nz \leq m$ .

The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

|         |                                                                                                                                                                                                                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         | If $jobz = 'V'$ , $nz = m$                                                                                                                                                                                                                                                                         |
| $w$     | (global ) array of size $n$<br>Upon successful exit, the first $m$ entries contain the selected eigenvalues in ascending order.                                                                                                                                                                    |
| $z$     | Block-cyclic array, global size $n * n$ , local size $l/d_z * LOC_c(jz+n-1)$ .<br>On exit, contains local pieces of distributed matrix $Z$ .                                                                                                                                                       |
| $work$  | On return, $work[0]$ contains the optimal amount of workspace required for efficient execution. If $jobz='N'$ $work[0]$ = optimal amount of workspace required to compute the eigenvalues. If $jobz='V'$ $work[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors. |
| $iwork$ | (local workspace) array<br>On return, $iwork[0]$ contains the amount of integer workspace required.                                                                                                                                                                                                |
| $info$  | (global )<br>= 0: successful exit<br>< 0: If the $i$ -th argument is an array and the $j$ -th-entry had an illegal value, then $info = -(i*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .                                                              |

## Application Notes

The distributed submatrices  $a(ia:*, ja:*)$  and  $z(iz:iz+m-1, jz:jz+n-1)$  must satisfy the following alignment properties:

1. Identical (quadratic) dimension:  $desc_a[m_- 1] = desc_z[m_- 1] = desc_a[n_- 1] = desc_z[n_- 1]$ ,
2. Quadratic conformal blocking:  $desc_a[mb_- 1] = desc_a[nb_- 1] = desc_z[mb_- 1] = desc_z[nb_- 1]$ ,  
 $desc_a[rsrc_- 1] = desc_z[rsrc_- 1]$
3.  $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

## Description

The `p?syevx` function computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix  $A$  by calling the recommended sequence of ScaLAPACK functions. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

*np* = the number of rows local to a given process.

*nq* = the number of columns local to a given process.

*jobz* (global) Must be '`N`' or '`V`'. Specifies if it is necessary to compute the eigenvectors:

If *jobz* = '`N`', then only eigenvalues are computed.

If *jobz* = '`V`', then eigenvalues and eigenvectors are computed.

*range* (global) Must be '`A`', '`V`', or '`I`'.

If *range* = '`A`', all eigenvalues will be found.

If *range* = '`V`', all eigenvalues in the half-open interval  $[vl, vu]$  will be found.

If *range* = '`I`', the eigenvalues with indices *il* through *iu* will be found.

*uplo* (global) Must be '`U`' or '`L`'.

Specifies whether the upper or lower triangular part of the symmetric matrix  $A$  is stored:

If *uplo* = '`U`', *a* stores the upper triangular part of  $A$ .

If *uplo* = '`L`', *a* stores the lower triangular part of  $A$ .

*n* (global) The number of rows and columns of the matrix  $A$  ( $n \geq 0$ ).

*a* (local).

Block cyclic array of global size  $n*n$  and local size  $lld_a * LOCr(ja+n-1)$ . On entry, the symmetric matrix  $A$ .

If *uplo* = '`U`', only the upper triangular part of  $A$  is used to define the elements of the symmetric matrix.

If  $uplo = 'L'$ , only the lower triangular part of  $A$  is used to define the elements of the symmetric matrix.

*ia, ja*

(global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A$ , respectively.

*descA*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

*vl, vu*

(global)  
If  $range = 'V'$ , the lower and upper bounds of the interval to be searched for eigenvalues;  $vl \leq vu$ . Not referenced if  $range = 'A'$  or  $'I'$ .

*il, iu*

(global)  
If  $range = 'I'$ , the indices of the smallest and largest eigenvalues to be returned.

Constraints:  $il \geq 1$

$\min(il, n) \leq iu \leq n$

Not referenced if  $range = 'A'$  or  $'V'$ .

*abstol*

(global).  
If  $jobz='V'$ , setting *abstol* to  $p?lamch(context, 'U')$  yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a, b]$  of width less than or equal to

$abstol + eps * \max(|a|, |b|),$

where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps*\*norm( $T$ ) will be used in its place, where norm( $T$ ) is the 1-norm of the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form.

Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold  $2*p?lamch('S')$  not zero. If this function returns with  $(\text{mod}(info, 2) \neq 0)$  or  $(\text{mod}(info/8, 2) \neq 0)$ , indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to  $2*p?lamch('S')$ .

*orfac*

(global).  
Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within  $tol=orfac*\text{norm}(A)$  of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of  $1.0e-3$  is used if *orfac* is negative. *orfac* should be identical on all processes.

*iz, jz*

(global) The row and column indices in the global matrix  $Z$  indicating the first row and the first column of the submatrix  $Z$ , respectively.

*descZ*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $Z$ .  $descZ[ctxt_ - 1]$  must equal  $descA[ctxt_ - 1]$ .

*work*

(local)

Array of size *lwork*.*lwork*(local) The size of the array *work*.See below for definitions of variables used to define *lwork*.If no eigenvectors are requested (*jobz* = 'N'), then *lwork*  $\geq 5*n + \max(5*nn, NB*(np0 + 1))$ .If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:
$$lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*NB*NB) + \text{ceil}(neig, \text{NPROW}*\text{NPCOL}) * nn$$
The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to *lwork*:
$$(\text{clustersize}-1)*n,$$
where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:
$$\{w[k - 1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1]) + orfac*2*norm(A)\},$$

where

*neig* = number of eigenvectors requested*nb* = *desca*[*mb*\_ - 1] = *desca*[*nb*\_ - 1] = *descz*[*mb*\_ - 1] = *descz*[*nb*\_ - 1];*nn* = max(*n*, *nb*, 2);*desca*[*rsrc*\_ - 1] = *desca*[*nb*\_ - 1] = *descz*[*rsrc*\_ - 1] = *descz*[*csrc*\_ - 1] = 0;*np0* = numroc(*nn*, *nb*, 0, 0, *NPROW*);*mq0* = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, *NPCOL*)*ceil*(*x*, *y*) is a ScaLAPACK function returning ceiling(*x/y*)If *lwork* is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, p?sygvx computes the eigenvalues and as many eigenvectors as possible.[Relationship between workspace, orthogonality & performance:](#)

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

$lwork \geq \max(lwork, 5*n + nsytrd\_lwopt)$ ,  
 where  $lwork$ , as defined previously, depends upon the number of eigenvectors requested, and

```

nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps;
anb = pjlaenv(desca[ctxt_ - 1], 3, 'p?sytrd', 'L', 0, 0, 0, 0);
sqnpc = int(sqrt(db1e(NPROW * NPCOL)));
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb);

```

numroc is a ScaLAPACK tool functions;  
 pjlaenv is a ScaLAPACK environmental inquiry function  
 MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs\_gridinfo.

For large  $n$ , no extra workspace is needed, however the biggest boost in performance comes for small  $n$ , so it is wise to provide the extra workspace (typically less than a megabyte per process).

If  $clustersize > n/sqrt(NPROW*NPCOL)$ , then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is,  $clustersize = n-1$ ) p?stein will perform no better than ?stein on single processor.

For  $clustersize = n/sqrt(NPROW*NPCOL)$  reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For  $clustersize > n/sqrt(NPROW*NPCOL)$  execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

$iwork$

(local) Workspace array.

$liwork$

(local), size of  $iwork$ .  $liwork \geq 6*nnp$

Where:  $nnp = \max(n, NPROW*NPCOL + 1, 4)$

If  $liwork = -1$ , then  $liwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

## Output Parameters

$a$

On exit, the lower triangle (if  $uplo = 'L'$ ) or the upper triangle (if  $uplo = 'U'$ ) of  $A$ , including the diagonal, is overwritten.

$m$

(global) The total number of eigenvalues found;  $0 \leq m \leq n$ .

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>nz</i>       | (global) Total number of eigenvectors computed. $0 \leq nz \leq m$ .<br>The number of columns of <i>z</i> that are filled.<br>If <i>jobz</i> ≠ 'V', <i>nz</i> is not referenced.<br>If <i>jobz</i> = 'V', <i>nz</i> = <i>m</i> unless the user supplies insufficient space and p?syevx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in <i>z</i> ( $m \leq descz[n_ - 1]$ ) and sufficient workspace to compute them. (See <i>lwork</i> ). p?syevx is always able to detect insufficient space without computation unless <i>range</i> = 'V'.                                                           |

| <i>iclustr</i>  | (global) Array of size $(2 * NPROW * NPCOL)$<br>This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see <i>lwork</i> , <i>orfac</i> and <i>info</i> ). Eigenvectors corresponding to clusters of eigenvalues indexed <i>iclustr(2*i-1)</i> to <i>iclustr(2*i)</i> , could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. <i>iclustr</i> is a zero terminated array. <i>iclustr[2*k - 1] ≠ 0</i> and <i>iclustr[2*k] = 0</i> if and only if <i>k</i> is the number of clusters.<br><i>iclustr</i> is not referenced if <i>jobz</i> = 'N'. |
| <i>gap</i>      | (global)<br>Array of size <i>NPROW*NPCOL</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*th cluster may be as high as  $(C*n) / gap[i - 1]$  where *C* is a small constant.

*info*

(global)

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i*\*100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info*> 0: if (mod(*info*, 2)≠0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*=2.0\*p?lamch('U').

If (mod(*info*/2, 2)≠0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4, 2)≠0), then space limit prevented p?syevxf from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If (mod(*info*/8, 2)≠0), then p?stebz failed to compute eigenvalues. Ensure *abstol*=2.0\*p?lamch('U').

---

#### NOTE

mod(*x*, *y*) is the integer remainder of *x/y*.

## Description

The `p?heev` function computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$  by calling the recommended sequence of ScaLAPACK functions. The function assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

## Input Parameters

$np$  = the number of rows local to a given process.

$nq$  = the number of columns local to a given process.

$jobz$  (global) Must be '`N`' or '`V`'.

Specifies if it is necessary to compute the eigenvectors:

If  $jobz = 'N'$ , then only eigenvalues are computed.

If  $jobz = 'V'$ , then eigenvalues and eigenvectors are computed.

$uplo$  (global) Must be '`U`' or '`L`'.

Specifies whether the upper or lower triangular part of the Hermitian matrix  $A$  is stored:

If  $uplo = 'U'$ ,  $a$  stores the upper triangular part of  $A$ .

If  $uplo = 'L'$ ,  $a$  stores the lower triangular part of  $A$ .

$n$  (global) The number of rows and columns of the matrix  $A$  ( $n \geq 0$ ).

$a$  (local).

Block cyclic array of global size  $n*n$  and local size  $lld\_a*LOCc(ja+n-1)$ . On entry, the Hermitian matrix  $A$ .

If  $uplo = 'U'$ , only the upper triangular part of  $A$  is used to define the elements of the Hermitian matrix.

If  $uplo = 'L'$ , only the lower triangular part of  $A$  is used to define the elements of the Hermitian matrix.

$ia, ja$  (global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A$ , respectively.

$desca$  (global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ . If  $desca[ctxt_ - 1]$  is incorrect, `p?heev` cannot guarantee correct error reporting.

$iz, jz$  (global) The row and column indices in the global matrix  $Z$  indicating the first row and the first column of the submatrix  $Z$ , respectively.

$descz$  (global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $Z$ .  $descz[ctxt_ - 1]$  must equal  $desca[ctxt_ - 1]$ .

$work$  (local).

Array of size  $lwork$ .

$lwork$  (local) The size of the array  $work$ .

If only eigenvalues are requested ( $jobz = 'N'$ ):

$lwork \geq \max(nb * (np0 + 1), 3) + 3 * n$

If eigenvectors are requested ( $jobz = 'V'$ ), then the amount of workspace required:

```
lwork ≥ (np0+nq0+nb) * nb + 3*n + n2
with nb = desca[mb_ - 1] = desca[nb_ - 1] = nb = descz[mb_ - 1] = descz[nb_ - 1]
np0 = numroc(nn, nb, 0, 0, NPROW).
nq0 = numroc(max(n, nb, 2), nb, 0, 0, NPCOL).
```

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

*rwork*

(local).

Workspace array of size *lrwork*.

*lrwork*

(local) The size of the array *rwork*.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested ( $jobz = 'N'$ ), then  $lrwork \geq 2*n$ .

If eigenvectors are requested ( $jobz = 'V'$ ), then  $lrwork \geq 2*n + 2*n-2$ .

If  $lrwork = -1$ , then  $lrwork$  is global input and a workspace query is assumed; the function only calculates the minimum size required for the *rwork* array. The required workspace is returned as the first element of *rwork*, and no error message is issued by pxerbla.

## Output Parameters

*a*

On exit, the lower triangle (if  $uplo = 'L'$ ), or the upper triangle (if  $uplo = 'U'$ ) of *A*, including the diagonal, is overwritten.

*w*

(global).

Array of size *n*. The first *m* elements contain the selected eigenvalues in ascending order.

*z*

(local).

Array, global size *n\*n*, local size *lld\_z\*LOCc(jz+n-1)*.

If  $jobz = 'V'$ , then on normal exit the first columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If  $jobz = 'N'$ , then *z* is not referenced.

*work[0]*

On exit, returns adequate workspace to allow optimal performance.

If  $jobz = 'N'$ , then *work[0]* = minimal workspace only for eigenvalues.

If  $jobz = 'V'$ , then *work[0]* = minimal workspace required to generate all the eigenvectors.

*rwork[0]* (local)  
 On output, *rwork[0]* returns workspace required to guarantee completion.

*info* (global)  
 If *info* = 0, the execution is successful.  
 If *info* < 0:  
   If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i*\*100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.  
   If *info* > 0:  
     If *info* = 1 through *n*, the *i*-th eigenvalue did not converge in [?steqr2](#) after a total of  $30*n$  iterations.  
     If *info* = *n*+1, then p?heev detected heterogeneity, and the accuracy of the results cannot be guaranteed.

```

## Include Files

- mkl\_scalapack.h

## Description

The p?heevd function computes all eigenvalues and eigenvectors of a complex Hermitian matrix *A* by using a divide and conquer algorithm.

## Input Parameters

*np* = the number of rows local to a given process.

*nq* = the number of columns local to a given process.

*jobz* (global) Must be 'N' or 'V'.

Specifies whether it is necessary to compute the eigenvectors:

If  $jobz = 'N'$ , then only eigenvalues are computed (**not yet implemented**).

If  $jobz = 'V'$ , then eigenvalues and eigenvectors are computed.

*uplo*

(global) Must be '*U*' or '*L*'.

Specifies whether the upper or lower triangular part of the Hermitian matrix *A* is stored:

If  $uplo = 'U'$ , *a* stores the upper triangular part of *A*.

If  $uplo = 'L'$ , *a* stores the lower triangular part of *A*.

*n*

(global) The number of rows and columns of the matrix *A* ( $n \geq 0$ ).

*a*

(local).  
Block cyclic array of global size  $n*n$  and local size  $l1d\_a*LOCc(ja+n-1)$ . On entry, the Hermitian matrix *A*.

If  $uplo = 'U'$ , only the upper triangular part of *A* is used to define the elements of the Hermitian matrix.

If  $uplo = 'L'$ , only the lower triangular part of *A* is used to define the elements of the Hermitian matrix.

*ia, ja*

(global) The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

*desca*

(global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *A*. If *desca[ctxt\_ - 1]* is incorrect, p?heevd cannot guarantee correct error reporting.

*iz, jz*

(global) The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

*descz*

(global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *Z*. *descz[ctxt\_ - 1]* must equal *desca[ctxt\_ - 1]*.

*work*

(local).

Array of size *lwork*.

*lwork*

(local) The size of the array *work*.

If eigenvalues are requested:

*lwork* =  $n + (nb0 + mq0 + nb)*nb$

with  $np0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPROW})$

$mq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

*rwork*

(local).

Workspace array of size *lrwork*.

*lrwork* (local) The size of the array *rwork*.  
 $lrwork \geq 1 + 9*n + 3*np*nq,$   
 with  $np = \text{numroc}(n, nb, myrow, irow, NPROW)$   
 $nq = \text{numroc}(n, nb, mycol, icol, NPCOL)$

*iwork* (local) Workspace array of size *liwork*.

*liwork* (local), size of *iwork*.  
 $liwork = 7*n + 8*ncol + 2.$

## Output Parameters

*a* On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

*w* (global).  
 Array of size *n*. If *info* = 0, *w* contains the eigenvalues in the ascending order.

*z* (local).  
 Array, global size  $n*n$ , local size  $lld_z * \text{LOCc}(jz+n-1)$ .  
 The *z* parameter contains the orthonormal eigenvectors of the matrix *A*.

*work[0]* On exit, returns adequate workspace to allow optimal performance.

*rwork[0]* (local)  
 On output, *rwork[0]* returns workspace required to guarantee completion.

*iwork[0]* (local).  
 On return, *iwork[0]* contains the amount of integer workspace required.

*info* (global)  
 If *info* = 0, the execution is successful.  
 If *info* < 0:  
 If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* =  $-(i*100+j)$ . If the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .  
 If *info* > 0:  
 If *info* = 1 through *n*, the *i*-th eigenvalue did not converge.

## Description

p?heevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$  distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix  $A$  is reduced to complex Hermitian tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in  $w$ . The eigenvector matrix  $Z$  is stored in 2D block-cyclic format distributed over all processors.

## Input Parameters

|              |                                                                                             |
|--------------|---------------------------------------------------------------------------------------------|
| <i>jobz</i>  | (global)                                                                                    |
|              | Specifies whether or not to compute the eigenvectors:                                       |
|              | = 'N': Compute eigenvalues only.                                                            |
|              | = 'V': Compute eigenvalues and eigenvectors.                                                |
| <i>range</i> | (global)                                                                                    |
|              | = 'A': all eigenvalues will be found.                                                       |
|              | = 'V': all eigenvalues in the interval [ $vl, vu$ ] will be found.                          |
|              | = 'I': the $il$ -th through $iu$ -th eigenvalues will be found.                             |
| <i>uplo</i>  | (global)                                                                                    |
|              | Specifies whether the upper or lower triangular part of the Hermitian matrix $A$ is stored: |
|              | = 'U': Upper triangular                                                                     |
|              | = 'L': Lower triangular                                                                     |
| <i>n</i>     | (global )                                                                                   |

The number of rows and columns of the matrix  $A$ .  $n \geq 0$

$a$  Block-cyclic array, global size  $n * n$ , local size  $lId_a * LOC_c(ja+n-1)$

Contains the local pieces of the Hermitian distributed matrix  $A$ . If  $uplo = 'U'$ , only the upper triangular part of  $a$  is used to define the elements of the Hermitian matrix. If  $uplo = 'L'$ , only the lower triangular part of  $a$  is used to define the elements of the Hermitian matrix.

$ia$  (global )

Global row index in the global matrix  $A$  that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

$ja$  (global )

Global column index in the global matrix  $A$  that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

$desca$  (global and local) array of size  $dlen_$ . (The ScaLAPACK descriptor length is  $dlen_ = 9$ .)

The array descriptor for the distributed matrix  $a$ . The descriptor stores details about the 2D block-cyclic storage, see the notes below. If  $desca$  is incorrect, p?heevr cannot work correctly.

Also note the array alignment requirements specified below

$vl$  (global)

If  $range = 'V'$ , the lower bound of the interval to be searched for eigenvalues. Not referenced if  $range = 'A'$  or  $'I'$ .

$vu$  (global)

If  $range = 'V'$ , the upper bound of the interval to be searched for eigenvalues. Not referenced if  $range = 'A'$  or  $'I'$ .

$il$  (global )

If  $range = 'I'$ , the index (from smallest to largest) of the smallest eigenvalue to be returned.  $il \geq 1$ .

Not referenced if  $range = 'A'$ .

$iu$  (global )

If  $range = 'I'$ , the index (from smallest to largest) of the largest eigenvalue to be returned.  $\min(il, n) \leq iu \leq n$ .

Not referenced if  $range = 'A'$ .

$iz$  (global )

Global row index in the global matrix  $Z$  that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

$jz$  (global )

Global column index in the global matrix  $Z$  that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

`descz`

(global and local) array of size `dlen_`.

The array descriptor for the distributed matrix  $z$ . `descz[ctxt_ - 1]` must equal `desca[ctxt_ - 1]`

`work`

(local workspace) array of size `lwork`

`lwork`

(local )

Size of `work` array, must be at least 3.

If only eigenvalues are requested:

$lwork \geq n + \max( nb * ( np00 + 1 ), nb * 3 )$

If eigenvectors are requested:

$lwork \geq n + ( np00 + mq00 + nb ) * nb$

For definitions of  $np00$  and  $mq00$ , see `lrwork`.

For optimal performance, greater workspace is needed, i.e.

$lwork \geq \max( lwork, nhetrld_lwork )$

Where `lwork` is as defined above, and

$nhetrld_lwork = n + 2 * ( anb + 1 ) * ( 4 * nps + 2 ) + ( nps + 1 ) * nps$

`ictxt = desca[ctxt_ - 1]`

`anb = pjlaenv( ictxt, 3, 'PCHEATTRD', 'L', 0, 0, 0, 0 )`

`sqnpc = sqrt( real( nprow * npcol ) )`

`nps = max( numroc( n, 1, 0, 0, sqnpc ), 2 * anb )`

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

`rwork`

(local workspace) array of size `lrwork`

`lrwork`

(local )

Size of `rwork`, must be at least 3.

See below for definitions of variables used to define `lrwork`.

If no eigenvectors are requested (`jobz = 'N'`) then

$lrwork \geq 2 + 5 * n + \max( 12 * n, nb * ( np00 + 1 ) )$

If eigenvectors are requested (`jobz = 'V'`) then the amount of workspace required is:

$lrwork \geq 2 + 5 * n + \max( 18 * n, np00 * mq00 + 2 * nb * nb ) +$

$( 2 + \text{ceil}( neig, nprow * npcol ) ) * n$

**NOTE**

`ceil(x,y)` is the ceiling of  $x/y$ .

---

Variable definitions:

$neig$  = number of eigenvectors requested

$nb = desc[mb\_ - 1] = desc[nb\_ - 1] = descz[mb\_ - 1] = descz[nb\_ - 1]$

$nn = \max(n, nb, 2)$

$desc[rsrc\_ - 1] = desc[csrc\_ - 1] = descz[rsrc\_ - 1] = descz[csrc\_ - 1] = 0$

$np00 = \text{numroc}(nn, nb, 0, 0, nprow)$

$mq00 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, npcol)$

`ceil(x,y)` is a ScaLAPACK function returning  $\text{ceiling}(x/y)$ , and  $nprow$  and  $npcol$  can be determined by calling the function `blacs_gridinfo`.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pixerbla`

$iwork$  (local workspace) array of size  $lwork$

$lwork$  (local )

size of  $iwork$

Let  $nnp = \max(n, nprow * ncol + 1, 4)$ . Then:

$lwork \geq 12 * nnp + 2 * n$  when the eigenvectors are desired

$lwork \geq 10 * nnp + 2 * n$  when only the eigenvalues have to be computed

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`

## OUTPUT Parameters

$a$  The lower triangle (if  $uplo='L'$ ) or the upper triangle (if  $uplo='U'$ ) of  $a$ , including the diagonal, is destroyed.

$m$  (global )

Total number of eigenvalues found.  $0 \leq m \leq n$ .

$nz$  (global )

Total number of eigenvectors computed.  $0 \leq nz \leq m$ .

The number of columns of  $z$  that are filled.

If  $jobz \neq 'V'$ ,  $nz$  is not referenced.

|         |                                                                                                                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         | If $jobz = 'V'$ , $nz = m$                                                                                                                                                                                                                                                                            |
| $w$     | (global ) array of size $n$<br>On normal exit, the first $m$ entries contain the selected eigenvalues in ascending order.                                                                                                                                                                             |

| $iwork$ | On return, $iwork[0]$ contains the amount of integer workspace required.                                                                                                                                                                                                                              |
| $info$  | (global )<br>= 0: successful exit<br>< 0: If the $i$ -th argument is an array and the $j$ -th entry had an illegal value, then $info = -(i*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .                                                                 |

## Application Notes

The distributed submatrices  $a(ia:*, ja:*)$  and  $z(iz:iz+m-1, jz:jz+n-1)$  must satisfy the following alignment properties:

1. Identical (quadratic) dimension:  $desc_a[m_ - 1] = desc_z[m_ - 1] = desc_a[n_ - 1] = desc_z[n_ - 1]$
2. Quadratic conformal blocking:  $desc_a[mb_ - 1] = desc_a[nb_ - 1] = desc_z[mb_ - 1] = desc_z[nb_ - 1]$ ,  
 $desc_a[rsrc_ - 1] = desc_z[rsrc_ - 1]$
3.  $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

## Description

The p?heevx function computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$  by calling the recommended sequence of ScaLAPACK functions. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

*np* = the number of rows local to a given process.

*nq* = the number of columns local to a given process.

*jobz* (global) Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

*range* (global) Must be 'A', 'V', or 'I'.

If *range* = 'A', all eigenvalues will be found.

If *range* = 'V', all eigenvalues in the half-open interval [vl, vu] will be found.

If *range* = 'I', the eigenvalues with indices *il* through *iu* will be found.

*uplo* (global) Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix  $A$  is stored:

If *uplo* = 'U',  $A$  stores the upper triangular part of  $A$ .

If  $uplo = 'L'$ ,  $a$  stores the lower triangular part of  $A$ .

$n$  (global) The number of rows and columns of the matrix  $A$  ( $n \geq 0$ ).

$a$  (local).

Block cyclic array of global size  $n*n$  and local size  $lld\_a*LOCc(ja+n-1)$ . On entry, the Hermitian matrix  $A$ .

If  $uplo = 'U'$ , only the upper triangular part of  $A$  is used to define the elements of the Hermitian matrix.

If  $uplo = 'L'$ , only the lower triangular part of  $A$  is used to define the elements of the Hermitian matrix.

$ia, ja$  (global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A$ , respectively.

$desca$  (global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ . If  $desca[ctxt_ - 1]$  is incorrect, p?heevx cannot guarantee correct error reporting.

$vl, vu$  (global)

If  $range = 'V'$ , the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if  $range = 'A'$  or  $'I'$ .

$il, iu$

(global) If  $range = 'I'$ , the indices of the smallest and largest eigenvalues to be returned.

Constraints:

$il \geq 1; \min(il, n) \leq iu \leq n$ .

Not referenced if  $range = 'A'$  or  $'V'$ .

$abstol$

(global). If  $jobz='V'$ , setting  $abstol$  to p?lamch(context, 'U') yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a, b]$  of width less than or equal to  $abstol + eps * \max(|a|, |b|)$ , where  $eps$  is the machine precision. If  $abstol$  is less than or equal to zero, then  $eps * norm(T)$  will be used in its place, where  $norm(T)$  is the 1-norm of the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form.

Eigenvalues are computed most accurately when  $abstol$  is set to twice the underflow threshold  $2*p?lamch('S')$ , not zero. If this function returns with  $((mod(info, 2) \neq 0) . or. (mod(info/8, 2) \neq 0))$ , indicating that some eigenvalues or eigenvectors did not converge, try setting  $abstol$  to  $2*p?lamch('S')$ .

---

#### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

$orfac$

(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within  $tol=orfac*\text{norm}(A)$  of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative.

*orfac* should be identical on all processes.

*iz, jz*

(global) The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

*descz*

(global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *Z*. *descz[ctxt\_ - 1]* must equal *desca[ctxt\_ - 1]*.

*work*

(local).

Array of size *lwork*.

*lwork*

(local) The size of the array *work*.

If only eigenvalues are requested:

*lwork*  $\geq n + \max(np0 + 1, 3)$

If eigenvectors are requested:

*lwork*  $\geq n + (np0 + mq0 + nb) * nb$

with *nq0* = *numroc(nn, nb, 0, 0, NPCOL)*.

*lwork*  $\geq 5*n + \max(5*nn, np0*mq0 + 2*nb*nb) + \text{ceil}(neig, \text{NPROW} * \text{NPCOL}) * nn$

For optimal performance, greater workspace is needed, that is

*lwork*  $\geq \max(lwork, nhetrld_lwork)$

where *lwork* is as defined above, and *nhetrld\_lwork* = *n + 2\*(anb + 1)\*(4\*nps + 2) + (nps + 1)\*nps*

*ictxt* = *desca[ctxt\_ - 1]*

*anb* = *pjlaenv(ictxt, 3, 'pchetrd', 'L', 0, 0, 0, 0)*

*sqnpc* = *sqrt(db1e(NPROW \* NPCOL))*

*nps* = *max(numroc(n, 1, 0, 0, sqnpc), 2\*anb)*

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pixerbla*.

*rwork*

(local)

Workspace array of size *lrwork*.

*lrwork*

(local) The size of the array *work*.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lrwork*  $\geq 5*nn + 4*n$ .

If eigenvectors are requested (`jobz = 'V'`), then the amount of workspace required to guarantee that all eigenvectors are computed is:

```
lrwork ≥ 4*n + max(5*nn, np0*mq0+2*nb*nb) + ceil(neig,
NPROW*NPCOL)*nn
```

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and `orfac` is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following values to `lrwork`:

```
(clustersize-1)*n,
```

where `clustersize` is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

```
{w[k - 1], ..., w[k+clustersize-2] | w[j] ≤
w[j-1]+orfac*2*norm(A)}.
```

Variable definitions:

`neig` = number of eigenvectors requested;

```
nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] =
```

```
descz[nb_ - 1];
```

```
nn = max(n, NB, 2);
```

```
desca[rsrc_ - 1] = desca[nb_ - 1] = descz[rsrc_ - 1] =
descz[csrc_ - 1] = 0;
```

```
np0 = numroc(nn, nb, 0, 0, NPROW);
```

```
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL);
```

`ceil(x, y)` is a ScaLAPACK function returning `ceiling(x/y)`

When `lrwork` is too small:

If `lwork` is too small to guarantee orthogonality, `p?heevx` attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If `lwork` is too small to compute all the eigenvectors requested, no computation is performed and `info= -23` is returned. Note that when `range='V'`, `p?heevx` does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when `range='V'` and as long as `lwork` is large enough to allow `p?heevx` to compute the eigenvalues, `p?heevx` will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If `clustersize ≥ n/sqrt(NPROW*NPCOL)`, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, `clustersize = n-1`) `p?stein` will perform no better than `?stein` on 1 processor.

For `clustersize = n/sqrt(NPROW*NPCOL)` reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For `clustersize > n/sqrt(NPROW*NPCOL)` execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

$iwork$

(local) Workspace array.

$liwork$

(local), size of  $iwork$ .

$liwork \geq 6 * nnp$

Where:  $nnp = \max(n, \text{NPROW} * \text{NPCOL} + 1, 4)$

If  $liwork = -1$ , then  $liwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

## Output Parameters

$a$

On exit, the lower triangle (if  $uplo = 'L'$ ), or the upper triangle (if  $uplo = 'U'$ ) of  $A$ , including the diagonal, is overwritten.

$m$

(global) The total number of eigenvalues found;  $0 \leq m \leq n$ .

$nz$

(global) Total number of eigenvectors computed.  $0 \leq nz \leq m$ .

The number of columns of  $z$  that are filled.

If  $jobz \neq 'V'$ ,  $nz$  is not referenced.

If  $jobz = 'V'$ ,  $nz = m$  unless the user supplies insufficient space and p?heevx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in  $z$  ( $m \leq \text{descz}[n_ - 1]$ ) and sufficient workspace to compute them. (See  $lwork$ ). p?heevx is always able to detect insufficient space without computation unless  $\text{range} = 'V'$ .

$w$

(global).  
Array of size  $n$ . The first  $m$  elements contain the selected eigenvalues in ascending order.

$z$

(local).

Array, global size  $n * n$ , local size  $lld_z * \text{LOCc}(jz + n - 1)$ .

If  $jobz = 'V'$ , then on normal exit the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of  $z$  contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in  $ifail$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

$work[0]$

On exit, returns adequate workspace to allow optimal performance.

$rwork$

(local).

Array of size  $lwork$ . On return,  $rwork[0]$  contains the optimal amount of workspace required for efficient execution.

If  $jobz='N'$   $rwork[0]$  = optimal amount of workspace required to compute eigenvalues efficiently.

If  $jobz='V'$   $rwork[0]$  = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If  $range='V'$ , it is assumed that all eigenvectors may be required.

$iwork[0]$

(local)

On return,  $iwork[0]$  contains the amount of integer workspace required.

$ifail$

(global)

Array of size  $n$ .

If  $jobz = 'V'$ , then on normal exit, the first  $m$  elements of  $ifail$  are zero. If  $(\text{mod}(info, 2) \neq 0)$  on exit, then  $ifail$  contains the indices of the eigenvectors that failed to converge.

If  $jobz = 'N'$ , then  $ifail$  is not referenced.

$iclustr$

(global)

Array of size  $2 * \text{NPROW} * \text{NPCOL}$ .

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see  $lwork$ ,  $orfac$  and  $info$ ). Eigenvectors corresponding to clusters of eigenvalues indexed  $iclustr[2*i - 2]$  to  $iclustr[2*i - 1]$ , could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

$iclustr$  is a zero terminated array. ( $iclustr[2*k - 1] \neq 0$  and  $iclustr[2*k] = 0$ ) if and only if  $k$  is the number of clusters.  $iclustr$  is not referenced if  $jobz = 'N'$ .

$gap$

(global)

Array of size  $(\text{NPROW} * \text{NPCOL})$

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array  $iclustr$ . As a result, the dot product between eigenvectors corresponding to the  $i$ -th cluster may be as high as  $(C * n) / gap(i)$  where  $C$  is a small constant.

$info$

(global)

If  $info = 0$ , the execution is successful.

If  $info < 0$ :

If the  $i$ -th argument is an array and the  $j$ -entry had an illegal value, then  $info = -(i * 100 + j)$ . If the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

If  $info > 0$ :

If  $(\text{mod}(info, 2) \neq 0)$ , then one or more eigenvectors failed to converge. Their indices are stored in  $ifail$ . Ensure  $abstol=2.0 * p\text{lamch}('U')$

If  $(\text{mod}(info/2, 2) \neq 0)$ , then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If  $(\text{mod}(info/4, 2) \neq 0)$ , then space limit prevented [p?syevx](#) from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If  $(\text{mod}(info/8, 2) \neq 0)$ , then [p?stebz](#) failed to compute eigenvalues.  
Ensure *abstol*= $2.0 * \text{p?lamch}('U')$ .

## Description

The `p?gesvd` function computes the singular value decomposition (SVD) of an *m*-by-*n* matrix *A*, optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where  $\Sigma$  is an *m*-by-*n* matrix that is zero except for its  $\min(m, n)$  diagonal elements, *U* is an *m*-by-*m* orthogonal matrix, and *V* is an *n*-by-*n* orthogonal matrix. The diagonal elements of  $\Sigma$  are the singular values of *A* and the columns of *U* and *V* are the corresponding right and left singular vectors, respectively. The singular values are returned in array *s* in decreasing order and only the first  $\min(m, n)$  columns of *U* and rows of *vt* = *V*<sup>T</sup> are computed.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**NOTE**

The distributed submatrix  $\text{sub}(A)$  must verify certain alignment properties. These expressions must be true:

- $mb\_a = nb\_a = nb$
- $iroffa = icoffa$

where:

- $iroffa = \text{mod}(ia-1, nb)$
- $icoffa = \text{mod}(ja-1, nb)$

**Input Parameters**

*mp* = number of local rows in  $A$  and  $U$

*nq* = number of local columns in  $A$  and  $V^T$

*size* =  $\min(m, n)$

*sizeq* = number of local columns in  $U$

*sizep* = number of local rows in  $V^T$

*jobu* (global) Specifies options for computing all or part of the matrix  $U$ .

If  $jobu = 'V'$ , the first *size* columns of  $U$  (the left singular vectors) are returned in the array  $u$ ;

If  $jobu = 'N'$ , no columns of  $U$  (no left singular vectors) are computed.

*jobvt* (global)

Specifies options for computing all or part of the matrix  $V^T$ .

If  $jobvt = 'V'$ , the first *size* rows of  $V^T$  (the right singular vectors) are returned in the array  $vt$ ;

If  $jobvt = 'N'$ , no rows of  $V^T$  (no right singular vectors) are computed.

*m* (global) The number of rows of the matrix  $A$  ( $m \geq 0$ ).

*n* (global) The number of columns in  $A$  ( $n \geq 0$ ).

*a* (local).

Block cyclic array, global size  $(m, n)$ , local size  $(mp, nq)$ .

*ia, ja* (global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A$ , respectively.

*desca* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix  $A$ .

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <i>iu, ju</i>   | (global) The row and column indices in the global matrix $U$ indicating the first row and the first column of the submatrix $U$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>descu</i>    | (global and local) array of size $dlen_{\_}$ . The array descriptor for the distributed matrix $U$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>ivt, jvt</i> | (global) The row and column indices in the global matrix $VT$ indicating the first row and the first column of the submatrix $VT$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>descvt</i>   | (global and local) array of size $dlen_{\_}$ . The array descriptor for the distributed matrix $VT$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>work</i>     | (local).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                 | Workspace array of size $lwork$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>lwork</i>    | (local) The size of the array <i>work</i> ;<br>$lwork > 2 + 6 * sizeb + \max(watobd, wbdtosvd),$ where $sizeb = \max(m, n)$ , and <i>watobd</i> and <i>wbdtosvd</i> refer, respectively, to the workspace required to bidiagonalize the matrix $A$ and to go from the bidiagonal matrix to the singular value decomposition $USVT$ .<br>For <i>watobd</i> , the following holds:<br>$watobd = \max(\max(wp?lange, wp?gebrd), \max(wp?lared1d, wp?lared2d)),$ where <i>wp?lange</i> , <i>wp?lared1d</i> , <i>wp?lared2d</i> , <i>wp?gebrd</i> are the workspaces required respectively for the subprograms <i>p?lange</i> , <i>p?lared1d</i> , <i>p?lared2d</i> , <i>p?gebrd</i> . Using the standard notation<br>$mp = \text{numroc}(m, mb, \text{MYROW}, desca[ctxt\_{\_} - 1], \text{NPROW}),$ $nq = \text{numroc}(n, nb, \text{MYCOL}, desca[lld\_{\_} - 1], \text{NPCOL}),$ the workspaces required for the above subprograms are<br>$wp?lange = mp,$ $wp?lared1d = nq0,$ $wp?lared2d = mp0,$ $wp?gebrd = nb * (mp + nq + 1) + nq,$ where <i>nq0</i> and <i>mp0</i> refer, respectively, to the values obtained at $\text{MYCOL} = 0$ and $\text{MYROW} = 0$ . In general, the upper limit for the workspace is given by a workspace required on processor (0,0):<br>$watobd \leq nb * (mp0 + nq0 + 1) + nq0.$ In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.<br>For <i>wbdtosvd</i> , the following holds:<br>$wbdtosvd = size * (wantu * nru + wantvt * ncvt) + \max(w?bdsqr, \max(wantu * wp?ormbrqln, wantvt * wp?ormbrprt)),$ where |

`wantu(wantvt) = 1`, if left/right singular vectors are wanted, and `wantu(wantvt) = 0`, otherwise. `w?bdsqr`, `wp?ormbrqln`, and `wp?ormbrprt` refer respectively to the workspace required for the subprograms `?bdsqr`, `p?ormbr(qln)`, and `p?ormbr(prt)`, where `qln` and `prt` are the values of the arguments `vect`, `side`, and `trans` in the call to `p?ormbr`. `nru` is equal to the local number of rows of the matrix  $U$  when distributed 1-dimensional "column" of processes. Analogously, `ncvt` is equal to the local number of columns of the matrix  $VT$  when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure `?bdsqr` requires

`w?bdsqr = max(1, 2*size + (2*size - 4)* max(wantu, wantvt))`  
on every processor. Finally,

`wp?ormbrqln = max((nb*(nb-1))/2, (sizeq+mp)*nb)+nb*nb,`

`wp?ormbrprt = max((mb*(mb-1))/2, (sizep+nq)*mb)+mb*mb,`

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum size for the work array. The required workspace is returned as the first element of `work` and no error message is issued by `pxerbla`.

`rwork`

Workspace array of size  $1 + 4*sizeb$ . Not used for `psgesvd` and `pdgesvd`.

## Output Parameters

`a`

On exit, the contents of `a` are destroyed.

`s`

(global).

Array of size `size`.

Contains the singular values of  $A$  sorted so that  $s(i) \geq s(i+1)$ .

`u`

(local).

local size  $mp*sizeq$ , global size  $m*size$

If `jobu = 'V'`, `u` contains the first  $\min(m, n)$  columns of  $U$ .

If `jobu = 'N'` or `'O'`, `u` is not referenced.

`vt`

(local).

local size  $(sizep, nq)$ , global size  $(size, n)$

If `jobvt = 'V'`, `vt` contains the first `size` rows of  $VT$  if `jobu = 'N'`, `vt` is not referenced.

`work`

On exit, if `info = 0`, then `work[0]` returns the required minimal size of `lwork`.

`rwork`

On exit, if `info = 0`, then `rwork[0]` returns the required size of `rwork`.

`info`

(global)

If `info = 0`, the execution is successful.

If `info < 0`, If `info = -i`, the `i`th parameter had an illegal value.

If `info > 0 i`, then if `?bdsqr` did not converge,

If  $\text{info} = \min(m, n) + 1$ , then p?gesvd has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?gesvd cannot be guaranteed.

## Description

The p?sygvx function computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \text{sub}(A) \text{ sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here  $x$  denotes eigen vectors,  $\lambda$  (*lambda*) denotes eigenvalues,  $\text{sub}(A)$  denoting  $A_{(ia:ia+n-1, ja:ja+n-1)}$  is assumed to symmetric, and  $\text{sub}(B)$  denoting  $B_{(ib:ib+n-1, jb:jb+n-1)}$  is also positive definite.

## Input Parameters

|               |                                                                                                                                                                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ibtype</i> | (global) Must be 1 or 2 or 3.<br>Specifies the problem type to be solved:<br>If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \lambda * \text{sub}(B) * x$ ;<br>If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \lambda * x$ ; |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

If *ibtype* = 3, the problem type is  $\text{sub}(B) * \text{sub}(A) * x = \lambda x$ .

*jobz*  
 (global) Must be 'N' or 'V'.  
 If *jobz* ='N', then compute eigenvalues only.  
 If *jobz* ='V', then compute eigenvalues and eigenvectors.

*range*  
 (global) Must be 'A' or 'V' or 'I'.  
 If *range* = 'A', the function computes all eigenvalues.  
 If *range* = 'V', the function computes eigenvalues in the interval: [*vl*, *vu*]  
 If *range* = 'I', the function computes eigenvalues with indices *il* through *iu*.

*uplo*  
 (global) Must be 'U' or 'L'.  
 If *uplo* = 'U', arrays *a* and *b* store the upper triangles of  $\text{sub}(A)$  and  $\text{sub}(B)$ ;  
 If *uplo* = 'L', arrays *a* and *b* store the lower triangles of  $\text{sub}(A)$  and  $\text{sub}(B)$ .  
 (global) The order of the matrices  $\text{sub}(A)$  and  $\text{sub}(B)$ ,  $n \geq 0$ .

*a*  
 (local)  
 Pointer into the local memory to an array of size  $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the  $n$ -by- $n$  symmetric distributed matrix  $\text{sub}(A)$ .  
 If *uplo* = 'U', the leading  $n$ -by- $n$  upper triangular part of  $\text{sub}(A)$  contains the upper triangular part of the matrix.  
 If *uplo* = 'L', the leading  $n$ -by- $n$  lower triangular part of  $\text{sub}(A)$  contains the lower triangular part of the matrix.

*ia, ja*  
 (global) The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

*desca*  
 (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *A*. If *desca[ctxt\_ - 1]* is incorrect, p?sygvx cannot guarantee correct error reporting.

*b*  
 (local).  
 Pointer into the local memory to an array of size  $lld\_b * LOCC(jb+n-1)$ . On entry, this array contains the local pieces of the  $n$ -by- $n$  symmetric distributed matrix  $\text{sub}(B)$ .  
 If *uplo* = 'U', the leading  $n$ -by- $n$  upper triangular part of  $\text{sub}(B)$  contains the upper triangular part of the matrix.  
 If *uplo* = 'L', the leading  $n$ -by- $n$  lower triangular part of  $\text{sub}(B)$  contains the lower triangular part of the matrix.

*ib, jb*  
 (global) The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

|                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <i>mod(x, y)</i> is the integer remainder of <i>x/y</i> . |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <hr/>                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>orfac</i>                                              | (global).<br>Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within <i>tol=orfac*norm(A)</i> of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i> ), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>iz, jz</i>                                             | (global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>descz</i>                                              | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz[ctxt_ - 1]</i> must equal <i>desca[ctxt_ - 1]</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>work</i>                                               | (local)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Workspace array of size *lwork*

*lwork*

(local)

Size of the array *work*. See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then  $lwork \geq 5*n + \max(5*nn, NB*(np0 + 1))$ .

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*nb*nb) + \text{ceil}(neig, \text{NPROW}*\text{NPCOL}) * nn$ .

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to *lwork*:

$(\text{clustersize}-1)*n$ ,

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

```
{w[k - 1], ..., w[k+clustersize - 2] | w[j] ≤ w[j - 1] +
orfac*2*norm(A)}
```

Variable definitions:

*neig* = number of eigenvectors requested,

*nb* = *descA*[*mb*\_ - 1] = *descA*[*nb*\_ - 1] = *descZ*[*mb*\_ - 1] = *descZ*[*nb*\_ - 1],

*nn* =  $\max(n, nb, 2)$ ,

*descA*[*rsrc*\_ - 1] = *descA*[*nb*\_ - 1] = *descZ*[*rsrc*\_ - 1] = *descZ*[*csrc*\_ - 1] = 0,

*np0* = *numroc*(*nn*, *nb*, 0, 0, *NPROW*),

*mq0* = *numroc*( $\max(neig, nb, 2)$ , *nb*, 0, 0, *NPCOL*)

*ceil(x, y)* is a ScaLAPACK function returning  $\text{ceiling}(x/y)$

If *lwork* is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, p?sygvx computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

$lwork \geq \max(lwork, 5*n + nsytrd_lwopt, nsygst_lwopt)$ , where

*lwork*, as defined previously, depends upon the number of eigenvectors requested, and

```

nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps+3)*nps
nsygst_lwopt = 2*np0*nb + nq0*nb + nb*nb
anb = pjlaenv(desca[ctxt_ - 1], 3, p?sytrd ', 'L', 0, 0, 0,
0)
sqnpc = int(sqrt(db1e(NPROW * NPCOL)))
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)
NB = desca[mb_ - 1]
np0 = numroc(n, nb, 0, 0, NPROW)
nq0 = numroc(n, nb, 0, 0, NPCOL)
numroc is a ScaLAPACK tool functions;
pjlaenv is a ScaLAPACK environmental inquiry function
MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function
blacs_gridinfo.
```

For large *n*, no extra workspace is needed, however the biggest boost in performance comes for small *n*, so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If *clustersize*  $\geq n/\sqrt{NPROW \cdot NPCOL}$ , then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, *clustersize* = *n*-1) *p?stein* will perform no better than *?stein* on a single processor.

For *clustersize* = *n*/ $\sqrt{NPROW \cdot NPCOL}$  reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize* > *n*/ $\sqrt{NPROW \cdot NPCOL}$  execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pixerbla*.

*iwork*

(local) Workspace array.

*liwork*

(local), size of *iwork*.

*liwork*  $\geq 6*nnp$

Where:

*nnp* = max(*n*, NPROW\*NPCOL + 1, 4)

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pixerbla*.

## Output Parameters

*a*

On exit,

If  $jobz = 'V'$ , and if  $info = 0$ ,  $\text{sub}(A)$  contains the distributed matrix  $Z$  of eigenvectors. The eigenvectors are normalized as follows:

```
for ibtype = 1 or 2, $Z^T * \text{sub}(B) * Z = I$;
for ibtype = 3, $Z^T * \text{inv}(\text{sub}(B)) * Z = I$.
```

If  $jobz = 'N'$ , then on exit the upper triangle (if  $uplo='U'$ ) or the lower triangle (if  $uplo='L'$ ) of  $\text{sub}(A)$ , including the diagonal, is destroyed.

*b*

On exit, if  $info \leq n$ , the part of  $\text{sub}(B)$  containing the matrix is overwritten by the triangular factor  $U$  or  $L$  from the Cholesky factorization  $\text{sub}(B) = U^T * U$  or  $\text{sub}(B) = L * L^T$ .

*m*

(global) The total number of eigenvalues found,  $0 \leq m \leq n$ .

*nz*

(global)  
Total number of eigenvectors computed.  $0 \leq nz \leq m$ . The number of columns of  $z$  that are filled.

If  $jobz \neq 'V'$ ,  $nz$  is not referenced.

If  $jobz = 'V'$ ,  $nz = m$  unless the user supplies insufficient space and p?sygvx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in  $z$  ( $m \leq \text{descz}(n_)$ ) and sufficient workspace to compute them. (See *lwork* below.) p?sygvx is always able to detect insufficient space without computation unless  $range='V'$ .

*w*

(global)  
Array of size  $n$ . On normal exit, the first  $m$  entries contain the selected eigenvalues in ascending order.

*z*

(local).

global size  $n * n$ , local size  $l1d\_z * \text{LOCc}(jz+n-1)$ .

If  $jobz = 'V'$ , then on normal exit the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of  $z$  contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If  $jobz = 'N'$ , then  $z$  is not referenced.

*work*

If  $jobz='N'$   $work[0]$  = optimal amount of workspace required to compute eigenvalues efficiently

If  $jobz = 'V'$   $work[0]$  = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If  $range='V'$ , it is assumed that all eigenvectors may be required.

*ifail*

(global)

Array of size  $n$ .

*ifail* provides additional information when *info*≠0

If ( $\text{mod}(\text{info}/16, 2) \neq 0$ ) then *ifail*[0] indicates the order of the smallest minor which is not positive definite. If ( $\text{mod}(\text{info}, 2) \neq 0$ ) on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions hold and *jobz* = 'V', then the first *m* elements of *ifail* are set to zero.

*iclustr*

(global)

Array of size  $(2 * \text{NPROW} * \text{NPCOL})$ . This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*[ $2*i - 2$ ] to *iclustr*[ $2*i - 1$ ], could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array.

(*iclustr*[ $2*k - 1$ ]≠0 *and* *iclustr*[ $2*k$ ]=0) if and only if *k* is the number of clusters *iclustr* is not referenced if *jobz* = 'N'.

*gap*

(global)

Array of size  $\text{NPROW} * \text{NPCOL}$ . This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as  $(C * n) / \text{gap}[i - 1]$ , where *C* is a small constant.

*info*

(global)

If *info* = 0, the execution is successful.

If *info* <0: the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i*\*100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0:

If ( $\text{mod}(\text{info}, 2) \neq 0$ ), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If ( $\text{mod}(\text{info}, 2, 2) \neq 0$ ), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If ( $\text{mod}(\text{info}/4, 2) \neq 0$ ), then space limit prevented p?sygvx from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If ( $\text{mod}(\text{info}/8, 2) \neq 0$ ), then p?stebz failed to compute eigenvalues.

If ( $\text{mod}(\text{info}/16, 2) \neq 0$ ), then *B* was not positive definite. *ifail*(1) indicates the order of the smallest minor which is not positive definite.

### Description

The p?hegvx function computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$\text{sub}(A) \cdot x = \lambda \cdot \text{sub}(B) \cdot x, \quad \text{sub}(A) \cdot \text{sub}(B) \cdot x = \lambda \cdot x, \quad \text{or} \quad \text{sub}(B) \cdot \text{sub}(A) \cdot x = \lambda \cdot x.$$

Here  $\text{sub}(A)$  denoting  $A(ia:ia+n-1, ja:ja+n-1)$  and  $\text{sub}(B)$  are assumed to be Hermitian and  $\text{sub}(B)$  denoting  $B(ib:ib+n-1, jb:jb+n-1)$  is also positive definite.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Input Parameters

*ibtype* (global) Must be 1 or 2 or 3.

Specifies the problem type to be solved:

If *ibtype* = 1, the problem type is

$\text{sub}(A) \cdot x = \lambda \cdot \text{sub}(B) \cdot x;$

If *ibtype* = 2, the problem type is

$\text{sub}(A) \cdot \text{sub}(B) \cdot x = \lambda \cdot x;$

If *ibtype* = 3, the problem type is

$\text{sub}(B) \cdot \text{sub}(A) \cdot x = \lambda \cdot x.$

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <i>ib, jb</i> | (global)<br>The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.                                                                                                                                                                                                                                                                                                                                                                       |

*descb*(global and local) array of size *dlen\_*.

The array descriptor for the distributed matrix  $B.\text{descb}[\text{ctxt}_\text{-1}]$  must be equal to  $\text{desca}[\text{ctxt}_\text{-1}]$ .

*vl, vu*

(global)

If  $\text{range} = \text{'V'}$ , the lower and upper bounds of the interval to be searched for eigenvalues.

If  $\text{range} = \text{'A'}$  or  $\text{'I'}$ , *vl* and *vu* are not referenced.

*il, iu*

(global)

If  $\text{range} = \text{'I'}$ , the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint:  $\text{il} \geq 1$ ,  $\min(\text{il}, n) \leq \text{iu} \leq n$

If  $\text{range} = \text{'A'}$  or  $\text{'V'}$ , *il* and *iu* are not referenced.

*abstol*

(global)

If  $\text{jobz} = \text{'V'}$ , setting *abstol* to  $\text{p?lamch}(\text{context}, \text{'U'})$  yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a, b]$  of width less than or equal to

$$\text{abstol} + \text{eps} * \max(|a|, |b|),$$

where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps*\* $\text{norm}(\mathbb{T})$  will be used in its place, where  $\text{norm}(\mathbb{T})$  is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold  $2 * \text{p?lamch}(\text{'S'})$  not zero. If this function returns with  $((\text{mod}(\text{info}, 2) \neq 0) . \text{or. } * (\text{mod}(\text{info}/8, 2) \neq 0))$ , indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to  $2 * \text{p?lamch}(\text{'S'})$ .

---

#### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

*orfac*

(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within  $\text{tol} = \text{orfac} * \text{norm}(A)$  of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0E-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

*iz, jz*

(global) The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

*descz*

(global and local) array of size *dlen\_*. The array descriptor for the distributed matrix  $Z.\text{descz}[\text{ctxt}_\text{-1}]$  must equal  $\text{desca}[\text{ctxt}_\text{-1}]$ .

*work* (local)  
 Workspace array of size *lwork*

*lwork* (local).  
 The size of the array *work*.  
 If only eigenvalues are requested:  

$$lwork \geq n + \max(NB * (np0 + 1), 3)$$
 If eigenvectors are requested:  

$$lwork \geq n + (np0 + mq0 + NB) * NB$$
 with  $nq0 = \text{numroc}(nn, NB, 0, 0, \text{NPCOL})$ .  
 For optimal performance, greater workspace is needed, that is  

$$lwork \geq \max(lwork, n, nhetrld_lwopt, nhegst_lwopt)$$
 where *lwork* is as defined above, and  

$$\begin{aligned} nhetrld_lwork &= 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps; \\ nhegst_lwopt &= 2 * np0 * nb + nq0 * nb + nb * nb \\ nb &= desca[mb_ - 1] \\ np0 &= \text{numroc}(n, nb, 0, 0, \text{NPROW}) \\ nq0 &= \text{numroc}(n, nb, 0, 0, \text{NPCOL}) \\ ictxt &= desca[ctxt_ - 1] \\ anb &= pjlaenv(ictxt, 3, 'p?hetrd', 'L', 0, 0, 0, 0) \\ sqnpsc &= \sqrt(\text{dbl}(NPROW * NPCOL)) \\ nps &= \max(\text{numroc}(n, 1, 0, 0, sqnpsc), 2 * anb) \end{aligned}$$
 numroc is a ScaLAPACK tool functions;  
 pjlaenv is a ScaLAPACK environmental inquiry function MYROW, MYCOL,  
 NPROW and NPCOL can be determined by calling the function  
 blacs\_gridinfo.  
 If *lwork* = -1, then *lwork* is global input and a workspace query is  
 assumed; the function only calculates the size required for optimal  
 performance for all work arrays. Each of these values is returned in the first  
 entry of the corresponding work arrays, and no error message is issued by  
 pxerbla.

*rwork* (local)  
 Workspace array of size *lrwork*.

*lrwork* (local) The size of the array *rwork*.  
 See below for definitions of variables used to define *lrwork*.  
 If no eigenvectors are requested (*jobz* = 'N'), then *lrwork*  $\geq 5 * nn + 4 * n$   
 If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace  
 required to guarantee that all eigenvectors are computed is:  

$$lrwork \geq 4 * n + \max(5 * nn, np0 * mq0) + \lceil neig, \\ NPROW * NPCOL \rceil * nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to *lwork*:

$(\text{clustersize}-1)*n,$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

```
{w[k - 1], ..., w[k+clustersize - 2] | w[j] ≤ w[j - 1] + orfac*2*norm(A)}
```

Variable definitions:

*neig* = number of eigenvectors requested;

```
nb = descra[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1];
```

```
nn = max(n, nb, 2);
```

```
descra[rsrc_ - 1] = desca[nb_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0;
```

```
np0 = numroc(nn, nb, 0, 0, NPROW);
```

```
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL);
```

*ceil(x, y)* is a ScaLAPACK function returning  $\text{ceiling}(x/y)$ .

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, p?hegvx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -25 is returned. Note that when *range*='V', p?hegvx does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow p?hegvx to compute the eigenvalues, p?hegvx will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If *clustersize* >  $n/\sqrt{NPROW*NPCOL}$ , then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, *clustersize* =  $n-1$ ) p?stein will perform no better than ?stein on 1 processor.

For *clustersize* =  $n/\sqrt{NPROW*NPCOL}$  reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize* >  $n/\sqrt{NPROW*NPCOL}$  execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxebla.

$iwork$

(local) Workspace array.

$liwork$

(local), size of  $iwork$ .

$liwork \geq 6 * nnp$

Where:  $nnp = \max(n, \text{NPROW} * \text{NPCOL} + 1, 4)$

If  $liwork = -1$ , then  $liwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxebla.

## Output Parameters

$a$

On exit, if  $jobz = 'V'$ , then if  $info = 0$ , sub( $A$ ) contains the distributed matrix  $Z$  of eigenvectors.

The eigenvectors are normalized as follows:

If  $ibtype = 1$  or  $2$ , then  $Z^H * \text{sub}(B) * Z = i$ ;

If  $ibtype = 3$ , then  $Z^H * \text{inv}(\text{sub}(B)) * Z = i$ .

If  $jobz = 'N'$ , then on exit the upper triangle (if  $uplo='U'$ ) or the lower triangle (if  $uplo='L'$ ) of sub( $A$ ), including the diagonal, is destroyed.

$b$

On exit, if  $info \leq n$ , the part of sub( $B$ ) containing the matrix is overwritten by the triangular factor  $U$  or  $L$  from the Cholesky factorization  $\text{sub}(B) = U^H * U$ , or  $\text{sub}(B) = L * L^H$ .

$m$

(global) The total number of eigenvalues found,  $0 \leq m \leq n$ .

$nz$

(global) Total number of eigenvectors computed.  $0 < nz < m$ . The number of columns of  $z$  that are filled.

If  $jobz \neq 'V'$ ,  $nz$  is not referenced.

If  $jobz = 'V'$ ,  $nz = m$  unless the user supplies insufficient space and p?hegsvx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in  $z$  ( $m \leq \text{descz}[n_ - 1]$ ) and sufficient workspace to compute them. (See  $lwork$  below.) The function p?hegsvx is always able to detect insufficient space without computation unless  $range = 'V'$ .

$w$

(global)

Array of size  $n$ . On normal exit, the first  $m$  entries contain the selected eigenvalues in ascending order.

$z$

(local).

global size  $n * n$ , local size  $lld_z * \text{LOCc}(jz + n - 1)$ .

If  $jobz = 'V'$ , then on normal exit the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of  $z$  contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in  $ifail$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

*work*

On exit,  $work[0]$  returns the optimal amount of workspace.

*rwork*

On exit,  $rwork[0]$  contains the amount of workspace required for optimal efficiency

If  $jobz='N'$   $rwork[0]$  = optimal amount of workspace required to compute eigenvalues efficiently

If  $jobz='V'$   $rwork[0]$  = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If  $range='V'$ , it is assumed that all eigenvectors may be required when computing optimal workspace.

*ifail*

(global)

Array of size  $n$ .

*ifail* provides additional information when  $info \neq 0$

If  $(mod(info/16, 2) \neq 0)$ , then  $ifail[0]$  indicates the order of the smallest minor which is not positive definite.

If  $(mod(info, 2) \neq 0)$  on exit, then  $ifail[0]$  contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions are held, and  $jobz = 'V'$ , then the first  $m$  elements of *ifail* are set to zero.

*iclustr*

(global)

Array of size  $(2 * NPROW * NPCOL)$ . This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed  $iclustr(2*i-1)$  to  $iclustr(2*i)$ , could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

*iclustr()* is a zero terminated array. ( $iclustr(2*k) \neq 0$  and  $clustr(2*k+1) = 0$ ) if and only if  $k$  is the number of clusters.

*iclustr* is not referenced if  $jobz = 'N'$ .

*gap*

(global)

Array of size  $NPROW * NPCOL$ .

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the  $i$ -th cluster may be as high as  $(C * n) / gap(i)$ , where  $C$  is a small constant.

*info* (global)

If *info* = 0, the execution is successful.

If *info* < 0: the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i*\*100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0:

If (mod(*info*, 2) ≠ 0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If (mod(*info*, 2, 2) ≠ 0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4, 2) ≠ 0), then space limit prevented p?sygvx from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If (mod(*info*/8, 2) ≠ 0), then p?stebz failed to compute eigenvalues.

If (mod(*info*/16, 2) ≠ 0), then *B* was not positive definite. *ifail*(1) indicates the order of the smallest minor which is not positive definite.

## ScaLAPACK Auxiliary Routines

### ScaLAPACK Auxiliary Routines

---

| Routine Name | Data Types | Description                                                                                                                                                     |
|--------------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p?lacgv      | c, z       | Conjugates a complex vector.                                                                                                                                    |
| p?max1       | c, z       | Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS p?amax, but using the absolute value to the real part). |
| pmpcol       | s, d       | <i>Finds the collaborators of a process.</i>                                                                                                                    |
| pmpim2       | s, d       | Computes the eigenpair range assignments for all processes.                                                                                                     |
| ?combamax1   | c, z       | Finds the element with maximum real part absolute value and its corresponding global index.                                                                     |
| p?sum1       | sc, dz     | Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.                                                        |
| p?dbtrsv     | s, d, c, z | Computes an LU factorization of a general tridiagonal matrix with no pivoting. The routine is called by p?dbtrs.                                                |
| p?dttrsv     | s, d, c, z | Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by p?dttrs.                          |
| p?gebal      | s, d       | Balances a general real/complex matrix.                                                                                                                         |

| Routine Name | Data Types | Description                                                                                                                                                                                                                                                                |
|--------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p?gebd2      | s, d, c, z | Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).                                                                                                                                                |
| p?gehd2      | s, d, c, z | Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).                                                                                                                                                |
| p?gelq2      | s, d, c, z | Computes an $LQ$ factorization of a general rectangular matrix (unblocked algorithm).                                                                                                                                                                                      |
| p?geql2      | s, d, c, z | Computes a $QL$ factorization of a general rectangular matrix (unblocked algorithm).                                                                                                                                                                                       |
| p?geqr2      | s, d, c, z | Computes a $QR$ factorization of a general rectangular matrix (unblocked algorithm).                                                                                                                                                                                       |
| p?gerq2      | s, d, c, z | Computes an $RQ$ factorization of a general rectangular matrix (unblocked algorithm).                                                                                                                                                                                      |
| p?getf2      | s, d, c, z | Computes an $LU$ factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).                                                                                                                                                |
| p?labrd      | s, d, c, z | Reduces the first $nb$ rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.                          |
| p?lacon      | s, d, c, z | Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.                                                                                                                                                            |
| p?laconsb    | s, d       | Looks for two consecutive small subdiagonal elements.                                                                                                                                                                                                                      |
| p?lacp2      | s, d, c, z | Copies all or part of a distributed matrix to another distributed matrix.                                                                                                                                                                                                  |
| p?lacp3      | s, d       | Copies from a global parallel array into a local replicated array or vice versa.                                                                                                                                                                                           |
| p?lacpy      | s, d, c, z | Copies all or part of one two-dimensional array to another.                                                                                                                                                                                                                |
| p?laevswp    | s, d, c, z | Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.                                                                                                                                                                              |
| p?lahrd      | s, d, c, z | Reduces the first $nb$ columns of a general rectangular matrix A so that elements below the $k^{th}$ subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A. |
| p?laiect     | s, d, c, z | Exploits IEEE arithmetic to accelerate the computations of eigenvalues.                                                                                                                                                                                                    |
| p?lamve      | s, d       | Copies all or part of one two-dimensional distributed array to another.                                                                                                                                                                                                    |
| p?lange      | s, d, c, z | Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.                                                                                                                             |
| p?lanhs      | s, d, c, z | Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.                                                                                                                               |

| Routine Name     | Data Types          | Description                                                                                                                                                                                          |
|------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p?lansy, p?lanhe | s, d, c, z/c<br>, z | Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix.                                        |
| p?lantr          | s, d, c, z          | Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.                                                                |
| p?lapiv          | s, d, c, z          | Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.                                                                                                   |
| p?laqge          | s, d, c, z          | Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.                                                                                                       |
| p?laqr0          | s, d                | Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.                                                                                    |
| p?laqr1          | s, d                | Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.                                                                                         |
| p?laqr2          | s, d                | Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation). |
| p?laqr3          | s, d                | Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation). |
| p?laqr5          | s, d                | Performs a single small-bulge multi-shift QR sweep.                                                                                                                                                  |
| p?laqsy          | s, d, c, z          | Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.                                                                                                                      |
| p?lared1d        | s, d                | Redistributes an array assuming that the input array <i>bycol</i> is distributed across rows and that all process columns contain the same copy of <i>bycol</i> .                                    |
| p?lared2d        | s, d                | Redistributes an array assuming that the input array <i>byrow</i> is distributed across columns and that all process rows contain the same copy of <i>byrow</i> .                                    |
| p?larf           | s, d, c, z          | Applies an elementary reflector to a general rectangular matrix.                                                                                                                                     |
| p?larfb          | s, d, c, z          | Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.                                                                                                      |
| p?larfc          | c, z                | Applies the conjugate transpose of an elementary reflector to a general matrix.                                                                                                                      |
| p?larfg          | s, d, c, z          | Generates an elementary reflector (Householder matrix).                                                                                                                                              |
| p?larft          | s, d, c, z          | Forms the triangular vector <i>T</i> of a block reflector $H=I-VTV^H$                                                                                                                                |
| p?larz           | s, d, c, z          | Applies an elementary reflector as returned by p?tzrzf to a general matrix.                                                                                                                          |
| p?larzb          | s, d, c, z          | Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.                                                                                           |

| Routine Name    | Data Types | Description                                                                                                                                            |
|-----------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| p?larzc         | c, z       | Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf to a general matrix.                                 |
| p?larzt         | s, d, c, z | Forms the triangular factor $T$ of a block reflector $H = I - VTV^H$ as returned by p?tzrzf.                                                           |
| p?lascl         | s, d, c, z | Multiplies a general rectangular matrix by a real scalar defined as $C_{\text{to}}/C_{\text{from}}$ .                                                  |
| p?laset         | s, d, c, z | Initializes the off-diagonal elements of a matrix to $\alpha$ and the diagonal elements to $\beta$ .                                                   |
| p?lasmsub       | s, d       | Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.                                                    |
| p?lassq         | s, d, c, z | Updates a sum of squares represented in scaled form.                                                                                                   |
| p?laswp         | s, d, c, z | Performs a series of row interchanges on a general rectangular matrix.                                                                                 |
| p?latra         | s, d, c, z | Computes the trace of a general square distributed matrix.                                                                                             |
| p?latrd         | s, d, c, z | Reduces the first $nb$ rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation. |
| p?latrz         | s, d, c, z | Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.                                           |
| p?lauu2         | s, d, c, z | Computes the product $UU^H$ or $L^H L$ , where U and L are upper or lower triangular matrices (local unblocked algorithm).                             |
| p?lauum         | s, d, c, z | Computes the product $UU^H$ or $L^H L$ , where U and L are upper or lower triangular matrices.                                                         |
| p?lawil         | s, d       | Forms the Wilkinson transform.                                                                                                                         |
| p?org2l/p?ung2l | s, d, c, z | Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).                          |
| p?org2r/p?ung2r | s, d, c, z | Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqr (unblocked algorithm).                           |
| p?orgl2/p?ungl2 | s, d, c, z | Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).                         |
| p?orgr2/p?ungr2 | s, d, c, z | Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf (unblocked algorithm).                         |
| p?orm2l/p?unm2l | s, d, c, z | Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).                      |
| p?orm2r/p?unm2r | s, d, c, z | Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqr (unblocked algorithm).                       |
| p?orml2/p?unml2 | s, d, c, z | Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).                     |
| p?ormr2/p?unmr2 | s, d, c, z | Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf (unblocked algorithm).                     |

| Routine Name    | Data Types   | Description                                                                                                                                                                   |
|-----------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p?pbtrs         | s, d, c, z   | Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf.                          |
| p?pttrs         | s, d, c, z   | Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf.                     |
| p?potf2         | s, d, c, z   | Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).                                                            |
| p?rot           | s, d         | Applies a planar rotation to two distributed vectors.                                                                                                                         |
| p?rscl          | s, d, cs, zd | Multiplies a vector by the reciprocal of a real scalar.                                                                                                                       |
| p?systs/p?hegs  | s, d, c, z   | Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm). |
| p?sytd2/p?hetd2 | s, d, c, z   | Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).                       |
| p?trord         | s, d         | Reorders the Schur factorization of a general matrix.                                                                                                                         |
| p?trsen         | s, d         | Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.       |
| p?trti2         | s, d, c, z   | Computes the inverse of a triangular matrix (local unblocked algorithm).                                                                                                      |
| ?lamsh          | s, d         | Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.                                                         |
| ?laqr6          | s, d         | Performs a single small-bulge multi-shift QR sweep collecting the transformations.                                                                                            |
| ?lar1va         | s, d         | <i>Computes scaled eigenvector corresponding to given eigenvalue.</i>                                                                                                         |
| ?laref          | s, d         | Applies Householder reflectors to matrices on either their rows or columns.                                                                                                   |
| ?larrb2         | s, d         | Provides limited bisection to locate eigenvalues for more accuracy.                                                                                                           |
| ?larrd2         | s, d         | Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.                                                                                              |
| ?larre2         | s, d         | Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.                                |
| ?larre2a        | s, d         | <i>Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.</i>                         |
| ?larrf2         | s, d         | Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.                                                                |
| ?larrv2         | s, d         | Computes the eigenvectors of the tridiagonal matrix $T = L^*D*L^T$ given $L$ , $D$ and the eigenvalues of $L^*D*L^T$ .                                                        |

| Routine Name | Data Types | Description                                                                                                                                                                  |
|--------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ?lasorte     | s, d       | Sorts eigenpairs by real and complex data types.                                                                                                                             |
| ?lasrt2      | s, d       | Sorts numbers in increasing or decreasing order.                                                                                                                             |
| ?stegr2      | s, d       | Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.                                                                                       |
| ?stegr2a     | s, d       | Computes selected eigenvalues and initial representations needed for eigenvector computations.                                                                               |
| ?stegr2b     | s, d       | From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. |
| ?stein2      | s, d       | Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.                                            |
| ?dbtf2       | s, d, c, z | Computes an <i>LU</i> factorization of a general band matrix with no pivoting (local unblocked algorithm).                                                                   |
| ?dbtrf       | s, d, c, z | Computes an <i>LU</i> factorization of a general band matrix with no pivoting (local blocked algorithm).                                                                     |
| ?dttrf       | s, d, c, z | Computes an <i>LU</i> factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).                                                              |
| ?dttrs v     | s, d, c, z | Solves a general tridiagonal system of linear equations using the <i>LU</i> factorization computed by ?dttrf.                                                                |
| ?pttrs v     | s, d, c, z | Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the $LDL^H$ factorization computed by ?pttrf.                                 |
| ?stegr2      | s, d       | Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit <i>QL</i> or <i>QR</i> method.                                   |
| ?trmv t      | s, d, c, z | Performs matrix-vector operations.                                                                                                                                           |
| pilaenv      | NA         | Returns the positive integer value of the logical blocking size.                                                                                                             |
| pilaenvx     | NA         | Called from the ScALAPACK routines to choose problem-dependent parameters for the local environment.                                                                         |

Notice revision #20201201

### p?lacgv

Conjugates a complex vector.

## Syntax

```
void pclacgv (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx);
```

```
void pzlacgv (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx);
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lacgv function conjugates a complex vector  $\text{sub}(X)$  of length  $n$ , where  $\text{sub}(X)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx = m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx = 1$ .

## Input Parameters

|              |                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>     | (global) The length of the distributed vector $\text{sub}(X)$ .                                                                                                           |
| <i>x</i>     | (local).<br>Pointer into the local memory to an array of size $lld_x * LOCc(n_x)$ . On entry the vector to be conjugated $x[i] = X(ix+(jx-1)*m_x+i*incx), 0 \leq i < n$ . |
| <i>ix</i>    | (global) The row index in the global matrix $X$ indicating the first row of $\text{sub}(X)$ .                                                                             |
| <i>jx</i>    | (global) The column index in the global matrix $X$ indicating the first column of $\text{sub}(X)$ .                                                                       |
| <i>descx</i> | (global and local) Array of size $dlen_=9$ . The array descriptor for the distributed matrix $X$ .                                                                        |
| <i>incx</i>  | (global) The global increment for the elements of $X$ . Only two values of <i>incx</i> are supported in this version, namely 1 and $m_x$ . <i>incx</i> must not be zero.  |

## Output Parameters

|          |                                                                                          |
|----------|------------------------------------------------------------------------------------------|
| <i>x</i> | (local).<br>On exit, the local pieces of conjugated distributed vector $\text{sub}(X)$ . |
|----------|------------------------------------------------------------------------------------------|

## p?max1

*Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS p?amax, but using the absolute value to the real part).*

## Syntax

```
void pcmax1 (MKL_INT *n , MKL_Complex8 *amax , MKL_INT *indx , MKL_Complex8 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx);
```

```
void pzmax1 (MKL_INT *n , MKL_Complex16 *amax , MKL_INT *indx , MKL_Complex16 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?max1` function computes the global index of the maximum element in absolute value of a distributed vector  $\text{sub}(X)$ . The global index is returned in `indx` and the value is returned in `amax`, where  $\text{sub}(X)$  denotes  $X(ix:ix+n-1, jx)$  if `incx = 1`,  $X(ix, jx:jx+n-1)$  if `incx = m_x`.

## Input Parameters

|                    |                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>     | (global). The number of components of the distributed vector $\text{sub}(X)$ . $n \geq 0$ .                                                                                                      |
| <code>x</code>     | (local)<br>Pointer into the local memory to an array of size $lld_x * LOCc(jx+n-1)$ . On entry this array contains the local pieces of the distributed vector $\text{sub}(X)$ .                  |
| <code>ix</code>    | (global) The row index in the global matrix $X$ indicating the first row of $\text{sub}(X)$ .                                                                                                    |
| <code>jx</code>    | (global) The column index in the global matrix $X$ indicating the first column of $\text{sub}(X)$ .                                                                                              |
| <code>descx</code> | (global and local) Array of size <code>dlen_</code> . The array descriptor for the distributed matrix $X$ .                                                                                      |
| <code>incx</code>  | (global). The global increment for the elements of $X$ . Only two values of <code>incx</code> are supported in this version, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero. |

## Output Parameters

|                   |                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>amax</code> | (global output).The absolute value of the largest entry of the distributed vector $\text{sub}(X)$ only in the scope of $\text{sub}(X)$ . |
| <code>indx</code> | (global output).The global index of the element of the distributed vector $\text{sub}(X)$ whose real part has maximum absolute value.    |

## pilaver

Returns the ScaLAPACK version.

## Syntax

```
void pilaver (MKL_INT* vers_major, MKL_INT* vers_minor, MKL_INT* vers_patch);
```

## Include Files

- mkl\_scalapack.h

## Description

This function returns the ScaLAPACK version.

## Output Parameters

|                         |                                     |
|-------------------------|-------------------------------------|
| <code>vers_major</code> | Return the ScaLAPACK major version. |
|-------------------------|-------------------------------------|

|                         |                                                            |
|-------------------------|------------------------------------------------------------|
| <code>vers_minor</code> | Return the ScaLAPACK minor version from the major version. |
| <code>vers_patch</code> | Return the ScaLAPACK patch version from the minor version. |

## pmpcol

*Finds the collaborators of a process.*

### Syntax

```
void pmpcol(MKL_INT* myproc, MKL_INT* nprocs, MKL_INT* iil, MKL_INT* needil, MKL_INT* neediu, MKL_INT* pmyils, MKL_INT* pmyius, MKL_INT* colbrt, MKL_INT* frstcl, MKL_INT* lastcl);
```

### Include Files

- `mkl_scalapack.h`

### Description

Using the output from `pmpim2` and given the information on eigenvalue clusters, `pmpcol` finds the collaborators of `myproc`.

Notice revision #20201201

### Input Parameters

|                     |                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>myproc</code> | The processor number, $0 \leq myproc < nprocs$ .                                                                                                                                                     |
| <code>nprocs</code> | The total number of processors available.                                                                                                                                                            |
| <code>iil</code>    | The index of the leftmost eigenvalue in the eigenvalue cluster.                                                                                                                                      |
| <code>needil</code> | The leftmost position in the eigenvalue cluster needed by <code>myproc</code> .                                                                                                                      |
| <code>neediu</code> | The rightmost position in the eigenvalue cluster needed by <code>myproc</code> .                                                                                                                     |
| <code>pmyils</code> | array<br>For each processor $p$ , $0 < p \leq nprocs$ , $pmyils[p-1]$ is the index of the first eigenvalue in the eigenvalue cluster to be computed.<br>$pmyils[p-1]$ equals zero if $p$ stays idle. |
| <code>pmyius</code> | array<br>For each processor $p$ , $pmyius[p-1]$ is the index of the last eigenvalue in the eigenvalue cluster to be computed.<br>$pmyius[p-1]$ equals zero if $p$ stays idle.                        |

### OUTPUT Parameters

|                                           |                                                      |
|-------------------------------------------|------------------------------------------------------|
| <code>colbrt</code>                       | Non-zero if <code>myproc</code> collaborates.        |
| <code>frstcl</code> , <code>lastcl</code> | First and last collaborator of <code>myproc</code> . |

**?combamax1**

*Finds the element with maximum real part absolute value and its corresponding global index.*

---

**Syntax**

```
void ccombamax1 (MKL_Complex8 *v1 , MKL_Complex8 *v2);
void zcombamax1 (MKL_Complex16 *v1 , MKL_Complex16 *v2);
```

**Include Files**

- mkl\_scalapack.h

**Description**

The ?combamax1 function finds the element having maximum real part absolute value as well as its corresponding global index.

**Input Parameters**

|    |                                                                                                          |
|----|----------------------------------------------------------------------------------------------------------|
| v1 | (local)                                                                                                  |
|    | Array of size 2. The first maximum absolute value element and its global index. v1[0]=amax, v1[1]=indx.  |
| v2 | (local)                                                                                                  |
|    | Array of size 2. The second maximum absolute value element and its global index. v2[0]=amax, v2[1]=indx. |

**Output Parameters**

|    |                                                                                        |
|----|----------------------------------------------------------------------------------------|
| v1 | (local).                                                                               |
|    | The first maximum absolute value element and its global index. v1[0]=amax, v1[1]=indx. |

**See Also**

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

**p?sum1**

*Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.*

---

**Syntax**

```
void pscsum1 (MKL_INT *n , float *asum , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx);
void pdzsum1 (MKL_INT *n , double *asum , MKL_Complex16 *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx);
```

**Include Files**

- mkl\_scalapack.h

**Description**

The p?sum1 function returns the sum of absolute values of a complex distributed vector sub(x) in asum, where sub(x) denotes  $x(ix:ix+n-1, jx:jx)$ , if incx = 1,  $X(ix:ix, jx:jx+n-1)$ , if incx = m\_x.

Based on `p?asum` from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

## Input Parameters

|                    |                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>     | (global). The number of components of the distributed vector $\text{sub}(x)$ . $n \geq 0$ .                                                                 |
| <code>x</code>     | (local )                                                                                                                                                    |
|                    | Pointer into the local memory to an array of size $lld_x * LOCc(jx+n-1)$ . This array contains the local pieces of the distributed vector $\text{sub}(X)$ . |
| <code>ix</code>    | (global) The row index in the global matrix $X$ indicating the first row of $\text{sub}(X)$ .                                                               |
| <code>jx</code>    | (global) The column index in the global matrix $X$ indicating the first column of $\text{sub}(X)$                                                           |
| <code>descx</code> | (local) Array of size <code>dlen_=9</code> . The array descriptor for the distributed matrix $X$ .                                                          |
| <code>incx</code>  | (global) The global increment for the elements of $X$ . Only two values of <code>incx</code> are supported in this version, namely 1 and $m_x$ .            |

## Output Parameters

|                   |                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------|
| <code>asum</code> | (local)                                                                                 |
|                   | The sum of absolute values of the distributed vector $\text{sub}(X)$ only in its scope. |

## `p?dbtrsv`

*Computes an LU factorization of a general triangular matrix with no pivoting. The function is called by `p?dbtrs`.*

## Syntax

```
void psdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , float *a , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT
*info);

void pddbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , double *a , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info);

void pcdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info);

void pzdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?dbtrsv` function solves a banded triangular system of linear equations

$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs)$  or

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs)$  (for real flavors);  $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs)$  (for complex flavors),

where  $A(1:n, ja:ja+n-1)$  is a banded triangular matrix factor produced by the Gaussian elimination code of `p?dbtrf` and is stored in  $A(1:n, ja:ja+n-1)$  and `af`. The matrix stored in  $A(1:n, ja:ja+n-1)$  is either upper or lower triangular according to `uplo`, and the choice of solving  $A(1:n, ja:ja+n-1)$  or  $A(1:n, ja:ja+n-1)^T$  is dictated by the user by the parameter `trans`.

The function `p?dbtrf` must be called first.

## Input Parameters

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uplo</code>  | (global)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                    | If <code>uplo='U'</code> , the upper triangle of $A(1:n, ja:ja+n-1)$ is stored,<br>if <code>uplo = 'L'</code> , the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.                                                                                                                                                                                                                                                                                                                                              |
| <code>trans</code> | (global)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                    | If <code>trans = 'N'</code> , solve with $A(1:n, ja:ja+n-1)$ ,<br>if <code>trans = 'C'</code> , solve with conjugate transpose $A(1:n, ja:ja+n-1)$ .                                                                                                                                                                                                                                                                                                                                                              |
| <code>n</code>     | (global) The order of the distributed submatrix $A$ ; ( $n \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>bwl</code>   | (global) Number of subdiagonals. $0 \leq bwl \leq n-1$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>bwu</code>   | (global) Number of subdiagonals. $0 \leq bwu \leq n-1$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>nrhs</code>  | (global) The number of right-hand sides; the number of columns of the distributed submatrix $B$ ( $nrhs \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>a</code>     | (local).<br>Pointer into the local memory to an array of size $lId\_a * LOCc(ja+n-1)$ , where $lId\_a \geq (bwl + bwu + 1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ unsymmetric banded distributed Cholesky factor $L$ or $L^T$ , represented in global $A$ as $A(1:n, ja:ja+n-1)$ . This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices. |
| <code>ja</code>    | (global) The index in the global matrix $A$ that points to the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).                                                                                                                                                                                                                                                                                                                                                     |
| <code>desca</code> | (global and local) array of size <code>dlen_</code> .<br>if 1d type ( <code>dtype_a = 501</code> or <code>502</code> ), <code>dlen \geq 7</code> ;<br>if 2d type ( <code>dtype_a = 1</code> ), <code>dlen \geq 9</code> . The array descriptor for the distributed matrix $A$ . Contains information of mapping of $A$ to memory.                                                                                                                                                                                 |

|              |                                                                                                                                                                                                                                                                    |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>b</i>     | (local)<br>Pointer into the local memory to an array of local lead dimension $l/d\_b \geq nb$ . On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$ .                                                                    |
| <i>ib</i>    | (global) The row index in the global matrix $B$ that points to the first row of the matrix to be operated on (which may be either all of $B$ or a submatrix of $B$ ).                                                                                              |
| <i>descb</i> | (global and local) array of size $dlen_$ .<br><br>if 1d type ( $dtype\_b = 502$ ), $dlen \geq 7$ ;<br><br>if 2d type ( $dtype\_b = 1$ ), $dlen \geq 9$ . The array descriptor for the distributed matrix $B$ . Contains information of mapping $B$ to memory.      |
| <i>laf</i>   | (local)<br>Size of user-input auxiliary fill-in space $af$ .<br><br>$laf \geq nb * (bw1 + bwu) + 6 * \max(bw1, bwu) * \max(bw1, bwu)$ . If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in $af[0]$ . |
| <i>work</i>  | (local).<br>Temporary workspace. This space may be overwritten in between function calls.<br><br><i>work</i> must be the size given in <i>lwork</i> .                                                                                                              |
| <i>lwork</i> | (local or global)<br>Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work[0]</i> and an error code is returned.<br><br>$lwork \geq \max(bw1, bwu) * nrhs$ .                            |

## Output Parameters

|             |                                                                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i>    | (local).<br>This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.                                                                                                                                        |
| <i>b</i>    | On exit, this contains the local piece of the solutions distributed matrix $X$ .                                                                                                                                                                                                                                   |
| <i>af</i>   | (local).<br>auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dbtrf</code> and is stored in <i>af</i> . If a linear system is to be solved using <code>p?dbtrf</code> after the factorization function, <i>af</i> must not be altered after the factorization. |
| <i>work</i> | On exit, <i>work[0]</i> contains the minimal <i>lwork</i> .                                                                                                                                                                                                                                                        |
| <i>info</i> | (local).<br>If <i>info</i> = 0, the execution is successful.                                                                                                                                                                                                                                                       |

$< 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $\text{info} = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $\text{info} = -i$ .

### p?dttrs

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges.  
The function is called by p?dttrs.

## Syntax

```
void psdttrs (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl , float
*d , float *du , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT

## Description

The p?dttrsfunction solves a tridiagonal triangular system of linear equations

$A(1:n, ja:ja+n-1)*X = B(ib:ib+n-1, 1 :nrhs)$  or

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1 :nrhs)$  for real flavors;  $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1 :nrhs)$  for complex flavors,

where  $A(1:n, ja:ja+n-1)$  is a tridiagonal matrix factor produced by the Gaussian elimination code of p?dttrf and is stored in  $A(1:n, ja:ja+n-1)$  and af.

The matrix stored in  $A(1:n, ja:ja+n-1)$  is either upper or lower triangular according to uplo, and the choice of solving  $A(1:n, ja:ja+n-1)$  or  $A(1:n, ja:ja+n-1)^T$  is dictated by the user by the parameter trans.

The function p?dttrf must be called first.

## Input Parameters

uplo

(global)

If uplo='U', the upper triangle of  $A(1:n, ja:ja+n-1)$  is stored,

if  $uplo = 'L'$ , the lower triangle of  $A(1:n, ja:ja+n-1)$  is stored.

*trans*  
(global)  
If  $trans = 'N'$ , solve with  $A(1:n, ja:ja+n-1)$ ,  
if  $trans = 'C'$ , solve with conjugate transpose  $A(1:n, ja:ja+n-1)$ .

*n*  
(global) The order of the distributed submatrix  $A$ ; ( $n \geq 0$ ).

*nrhs*  
(global) The number of right-hand sides; the number of columns of the distributed submatrix  $B(ib:ib+n-1, 1:nrhs)$ . ( $nrhs \geq 0$ ).

*dl*  
(local).  
Pointer to local part of global vector storing the lower diagonal of the matrix.  
Globally,  $dl[0]$  is not referenced, and  $dl$  must be aligned with  $d$ .  
Must be of size  $\geq nb\_a$ .

*d*  
(local).  
Pointer to local part of global vector storing the main diagonal of the matrix.

*du*  
(local).  
Pointer to local part of global vector storing the upper diagonal of the matrix.  
Globally,  $du[n-1]$  is not referenced, and  $du$  must be aligned with  $d$ .

*ja*  
(global) The index in the global matrix  $A$  that points to the start of the matrix to be operated on (which may be either all of  $A$  or a submatrix of  $A$ ).

*desca*  
(global and local) array of size  $dlen_$ .  
if 1d type ( $dtype\_a = 501$  or  $502$ ),  $dlen \geq 7$ ;  
if 2d type ( $dtype\_a = 1$ ),  $dlen \geq 9$ .  
The array descriptor for the distributed matrix  $A$ . Contains information of mapping of  $A$  to memory.

*b*  
(local)  
Pointer into the local memory to an array of local lead dimension  $lhd\_b \geq nb$ .  
On entry, this array contains the local pieces of the right-hand sides  $B(ib:ib+n-1, 1 : nrhs)$ .

*ib*  
(global) The row index in the global matrix  $B$  that points to the first row of the matrix to be operated on (which may be either all of  $B$  or a submatrix of  $B$ ).

*descb*  
(global and local) array of size  $dlen_$ .  
if 1d type ( $dtype\_b = 502$ ),  $dlen \geq 7$ ;  
if 2d type ( $dtype\_b = 1$ ),  $dlen \geq 9$ .  
The array descriptor for the distributed matrix  $B$ . Contains information of mapping  $B$  to memory.

*laf*  
(local).

Size of user-input auxiliary fill-in space  $af$ .

$laf \geq 2 * (nb + 2)$ . If  $laf$  is not large enough, an error code is returned and the minimum acceptable size will be returned in  $af[0]$ .

$work$

(local).

Temporary workspace. This space may be overwritten in between function calls.

$work$  must be the size given in  $lwork$ .

$lwork$

(local or global)

Size of user-input workspace  $work$ . If  $lwork$  is too small, the minimal acceptable size will be returned in  $work[0]$  and an error code is returned.

$lwork \geq 10 * n * p * c o l + 4 * n * r h s$ .

## Output Parameters

$d1$

(local).

On exit, this array contains information containing the factors of the matrix.

$d$

On exit, this array contains information containing the factors of the matrix. Must be of size  $\geq nb\_a$ .

$b$

On exit, this contains the local piece of the solutions distributed matrix X.

$af$

(local).

Auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?dttrf` and is stored in  $af$ . If a linear system is to be solved using `p?dttrs` after the factorization function,  $af$  must not be altered after the factorization.

$work$

On exit,  $work[0]$  contains the minimal  $lwork$ .

$info$

(local).

If  $info = 0$ , the execution is successful.

If  $info < 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j - 1$ , had an illegal value, then  $info = -(i * 100 + j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## `p?gebal`

Balances a general real/complex matrix.

---

## Syntax

```
void psgebal(char* job, MKL_INT* n, float* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT* ihi, float* scale, MKL_INT* info);

void pdgebal(char* job, MKL_INT* n, double* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT* ihi, double* scale, MKL_INT* info);

void pcgebal(char* job, MKL_INT* n, complex float* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT* ihi, float* scale, MKL_INT* info);
```

---

```
void pzgebal(char* job, MKL_INT* n, complex double* a, MKL_INT* desca, MKL_INT* ilo,
MKL_INT* ihi, double* scale, MKL_INT* info);
```

## Include Files

- mkl\_scalapack.h

## Description

p?gebal balances a general real/complex matrix  $A$ . This involves, first, permuting  $A$  by a similarity transformation to isolate eigenvalues in the first  $1$  to  $ilo-1$  and last  $ihi+1$  to  $n$  elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns  $ilo$  to  $ihi$  to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

## Input Parameters

|                                                                                                                                    |                                                                                                                                                    |

## OUTPUT Parameters

|                 |                                                                                                                                                                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i>        | On exit, <i>a</i> is overwritten by the balanced matrix $A$ .<br>If <i>job</i> = 'N', <i>a</i> is not referenced.<br>See Notes for further details.                                                                                                                                                                      |
| <i>ilo, ihi</i> | (global )<br><i>ilo</i> and <i>ihi</i> are set to integers such that on exit matrix elements $A(i,j)$ are zero if $i > j$ and $j = 1,...,ilo-1$ or $i = ihi+1,...,n$ .<br>If <i>job</i> = 'N' or 'S', <i>ilo</i> = 1 and <i>ihi</i> = <i>n</i> .                                                                         |
| <i>scale</i>    | (global ) array of size <i>n</i> .<br>Details of the permutations and scaling factors applied to <i>a</i> . If $pj$ is the index of the row and column interchanged with row and column $j$ and $dj$ is the scaling factor applied to row and column $j$ , then<br>$scale[j-1] = pj$ for $j = 1,...,ilo-1, ihi+1,..., n$ |

*scale[j-1] = dj* for  $j = \text{ilo}, \dots, \text{ih}i$

The order in which the interchanges are made is  $n$  to  $\text{ih}i+1$ , then 1 to  $\text{ilo}-1$ .

*info*

(global )

= 0: successful exit.

< 0: if  $\text{info} = -i$ , the  $i$ -th argument had an illegal value.

## Application Notes

The permutations consist of row and column interchanges which put the matrix in the form

$$PAP = \begin{pmatrix} T_1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T_2 \end{pmatrix}$$

where  $T_1$  and  $T_2$  are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices  $\text{ilo}$  and  $\text{ih}i$  mark the starting and ending columns of the submatrix  $B$ . Balancing consists of applying a diagonal similarity transformation  $D^{-1}BD$  to make the 1-norms of each row of  $B$  and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} I_1 & X & Y \\ 0 & D^{-1}BD & D^{-1}Z \\ 0 & 0 & I_2 \end{pmatrix}$$

Information about the permutations  $P$  and the diagonal matrix  $D$  is returned in the vector `scale`.

```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?gebd2` function reduces a real/complex general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$  to upper or lower bidiagonal form  $B$  by an orthogonal/unitary transformation:

$$Q^T \text{sub}(A) P = B.$$

If  $m \geq n$ ,  $B$  is the upper bidiagonal; if  $m < n$ ,  $B$  is the lower bidiagonal.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <i>ia, ja</i> | (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>desca</i>  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>work</i>   | (local).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|               | This is a workspace array of size <i>lwork</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>lwork</i>  | (local or global)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|               | The size of the array <i>work</i> .<br><br><i>lwork</i> is local input and must be at least $lwork \geq \max(mpa0, nqa0)$ ,<br>where $nb = mb\_a = nb\_a$ , $iroffa = \text{mod}(ia-1, nb)$ ,<br>$iarow = \text{indxg2p}(ia, nb, myrow, rsrc\_a, nprow)$ ,<br>$iacol = \text{indxg2p}(ja, nb, mycol, csric\_a, npcol)$ ,<br>$mpa0 = \text{numroc}(m+iroffa, nb, myrow, iarow, nprow)$ ,<br>$nqa0 = \text{numroc}(n+icoffa, nb, mycol, iacol, npcol)$ .<br><code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <code>myrow</code> , <code>mycol</code> , <code>nprow</code> , and <code>npcol</code> can be determined by calling the function <code>blacs_gridinfo</code> .<br>If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <a href="#">pxerbla</a> . |

## Output Parameters

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i> | (local).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|          | On exit, if $m \geq n$ , the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix $B$ ; the elements below the diagonal, with the array <i>tauq</i> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors, and the elements above the first superdiagonal, with the array <i>taup</i> , represent the orthogonal matrix $P$ as a product of elementary reflectors. If $m < n$ , the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix $B$ ; the elements below the first subdiagonal, with the array <i>tauq</i> , represent the |

orthogonal/unitary matrix  $Q$  as a product of elementary reflectors, and the elements above the diagonal, with the array  $taup$ , represent the orthogonal matrix  $P$  as a product of elementary reflectors. See *Applications Notes* below.

 $d$ 

(local)

Array of size  $\text{LOCc}(ja+\min(m, n)-1)$  if  $m \geq n$ ;  $\text{LOCr}(ia+\min(m, n)-1)$  otherwise. The distributed diagonal elements of the bidiagonal matrix  $B$ :  $d[i] = A(i+1, i+1)$ ,  $i=0, 1, \dots, \text{size}(d) - 1$ .  $d$  is tied to the distributed matrix  $A$ .

 $e$ 

(local)

Array of size  $\text{LOCc}(ja+\min(m, n)-1)$  if  $m \geq n$ ;  $\text{LOCr}(ia+\min(m, n)-2)$  otherwise. The distributed diagonal elements of the bidiagonal matrix  $B$ :

if  $m \geq n$ ,  $e[i] = A(i+1, i+2)$  for  $i = 0, 1, \dots, n-2$ ;

if  $m < n$ ,  $e[i] = A(i+2, i+1)$  for  $i = 0, 1, \dots, m-2$ .  $e$  is tied to the distributed matrix  $A$ .

 $tauq$ 

(local).

Array of size  $\text{LOCc}(ja+\min(m, n)-1)$ . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix  $Q$ .  $tauq$  is tied to the distributed matrix  $A$ .

 $taup$ 

(local).

Array of size  $\text{LOCr}(ia+\min(m, n)-1)$ . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix  $P$ .  $taup$  is tied to the distributed matrix  $A$ .

 $work$ 

On exit,  $work[0]$  returns the minimal and optimal  $lwork$ .

 $info$ 

(local)

If  $info = 0$ , the execution is successful.

If  $info < 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## Application Notes

The matrices  $Q$  and  $P$  are represented as products of elementary reflectors:

If  $m \geq n$ ,

$$Q = H(1) * H(2) * \dots * H(n), \text{ and } P = G(1) * G(2) * \dots * G(n-1)$$

Each  $H(i)$  and  $G(i)$  has the form:

$$H(i) = I - tauq * v * v', \text{ and } G(i) = I - taup * u * u',$$

where  $tauq$  and  $taup$  are real/complex scalars, and  $v$  and  $u$  are real/complex vectors.  $v(1: i-1) = 0$ ,  $v(i) = 1$ , and  $v(i+1:m)$  is stored on exit in

$$A(ia+i-ia+m-1, ja+i-1);$$

$u(1:i) = 0$ ,  $u(i+1) = 1$ , and  $u(i+2:n)$  is stored on exit in  $A(ia+i-1, ja+i+1:ja+n-1)$ ;

$\tau_{aq}$  is stored in  $\tau_{aq}[ja+i-2]$  and  $\tau_{ap}$  in  $\tau_{ap}[ia+i-2]$ .

If  $m < n$ ,

$v(1:i) = 0$ ,  $v(i+1) = 1$ , and  $v(i+2:m)$  is stored on exit in  $A(ia+i+1:ia+m-1, ja+i-1)$ ;

$u(1:i-1) = 0$ ,  $u(i) = 1$ , and  $u(i+1:n)$  is stored on exit in  $A(ia+i-1, ja+i:ja+n-1)$ ;

$\tau_{aq}$  is stored in  $\tau_{aq}[ja+i-2]$  and  $\tau_{ap}$  in  $\tau_{ap}[ia+i-2]$ .

The contents of  $\text{sub}(A)$  on exit are illustrated by the following examples:

$m = 6$  and  $n = 5$  ( $m > n$ ) :

$$\begin{bmatrix} d & e & u_1 & u_1 & u_1 \\ v_1 & d & e & u_2 & u_2 \\ v_1 & v_2 & d & e & u_3 \\ v_1 & v_2 & v_3 & d & e \\ v_1 & v_2 & v_3 & v_4 & d \\ v_1 & v_2 & v_3 & v_4 & v_5 \end{bmatrix}$$

$m = 5$  and  $n = 6$  ( $m < n$ ) :

$$\begin{bmatrix} d & u_1 & u_1 & u_1 & u_1 & u_1 \\ e & d & u_2 & u_2 & u_2 & u_2 \\ v_1 & e & d & u_3 & u_3 & u_3 \\ v_1 & v_2 & e & d & u_4 & u_4 \\ v_1 & v_2 & v_3 & e & d & u_5 \end{bmatrix}$$

where  $d$  and  $e$  denote diagonal and off-diagonal elements of  $B$ ,  $vi$  denotes an element of the vector defining  $H(i)$ , and  $ui$  an element of the vector defining  $G(i)$ .

## Description

The `p?gehd2` function reduces a real/complex general distributed matrix  $\text{sub}(A)$  to upper Hessenberg form  $H$  by an orthogonal/unitary similarity transformation:  $Q^* \text{sub}(A) Q = H$ , where  $\text{sub}(A) = A(ia+n-1 : ia + n-1, ja+n-1 : ja+n-1)$ .

## Input Parameters

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>        | (global) The order of the distributed submatrix $A$ . ( $n \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>ilo, ihi</code> | (global) It is assumed that the matrix $\text{sub}(A)$ is already upper triangular in rows $ia : ia+ilo-2$ and $ia+ihi : ia+n-1$ and columns $ja : ja+jlo-2$ and $ja+jhi : ja+n-1$ . See <i>Application Notes</i> for further information.<br><br>If $n \geq 0, 1 \leq ilo \leq ihi \leq n$ ; otherwise set $ilo = 1, ihi = n$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> . |

## Output Parameters

|                  |                                                                                                                                                                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a</code>   | (local). On exit, the upper triangle and the first subdiagonal of $\text{sub}(A)$ are overwritten with the upper Hessenberg matrix $H$ , and the elements below the first subdiagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors. (see <i>Application Notes</i> below). |
| <code>tau</code> | (local).                                                                                                                                                                                                                                                                                                                                          |

Array of size  $\text{LOCC}(ja+n-2)$  The scalar factors of the elementary reflectors (see *Application Notes* below). Elements  $ja:ja+ilo-2$  and  $ja+ihi:ja+n-2$  of the global vector  $\tau$  are set to zero.  $\tau$  is tied to the distributed matrix A.

*work* On exit,  $\text{work}[0]$  returns the minimal and optimal  $\text{lwork}$ .

*info* (local)

If  $\text{info} = 0$ , the execution is successful.

If  $\text{info} < 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $\text{info} = - (i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $\text{info} = -i$ .

## Application Notes

The matrix Q is represented as a product of  $(ihi-ilo)$  elementary reflectors

$$Q = H(ilo) * H(ilo+1) * \dots * H(ihi-1).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v'$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1: i)=0$ ,  $v(i+1)=1$  and  $v(ihi+1:n)=0$ ;  $v(i+2:ihi)$  is stored on exit in  $A(ia+ilo+i:ia+ihi-1, ia+ilo+i-2)$ , and  $\tau$  in  $\tau[ja+ilo+i-3]$ .

The contents of  $A(ia:ia+n-1, ja:ja+n-1)$  are illustrated by the following example, with  $n = 7$ ,  $ilo = 2$  and  $ihi = 6$ :

| on entry                                                                                                                                                                                                                                | on exit                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \end{bmatrix}$ | $\begin{bmatrix} a & a & h & h & h & h & a \\ a & h & h & h & h & h & a \\ h & h & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ & & & & & & a \end{bmatrix}$ |

where  $a$  denotes an element of the original matrix sub( $A$ ),  $h$  denotes a modified element of the upper Hessenberg matrix  $H$ , and  $vi$  denotes an element of the vector defining  $H(ja+ilo+i-2)$ .

## Description

The p?gelq2function computes an  $LQ$  factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = L*Q$ .

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>      | (global)                                                                                                                                                                                                                                                                                                                                                                                                       |
|               | The number of rows of the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).                                                                                                                                                                                                                                                                                                                                 |
| <i>n</i>      | (global)                                                                                                                                                                                                                                                                                                                                                                                                       |
|               | The number of columns of the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).                                                                                                                                                                                                                                                                                                                              |
| <i>a</i>      | (local).                                                                                                                                                                                                                                                                                                                                                                                                       |
|               | Pointer into the local memory to an array of size $lloc_a * loc_c(ja+n-1)$ .<br>On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ which is to be factored.                                                                                                                                                                                                 |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                  |
| <i>desca</i>  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                               |
| <i>work</i>   | (local).                                                                                                                                                                                                                                                                                                                                                                                                       |
|               | This is a workspace array of size $lwork$ .                                                                                                                                                                                                                                                                                                                                                                    |
| <i>lwork</i>  | (local or global)                                                                                                                                                                                                                                                                                                                                                                                              |
|               | The size of the array <i>work</i> .<br><br><i>lwork</i> is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$ ,<br>where $iwoff = \text{mod}(ia-1, mb\_a)$ , $icoff = \text{mod}(ja-1, nb\_a)$ ,<br>$iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$ ,<br>$iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol)$ ,<br>$mp0 = \text{numroc}(m+iwoff, mb\_a, myrow, iarow, nprow)$ , |

`nq0 = numroc(n+icoff, nb_a, mycol, iacol, npcol),`  
`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

## Output Parameters

|                   |                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a</code>    | (local).<br><br>On exit, the elements on and below the diagonal of sub( $A$ ) contain the $m$ by $\min(m,n)$ lower trapezoidal matrix $L$ ( $L$ is lower triangular if $m \leq n$ ); the elements above the diagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below). |
| <code>tau</code>  | (local).<br><br>Array of size $LOCr(ia+\min(m, n)-1)$ . This array contains the scalar factors of the elementary reflectors. <code>tau</code> is tied to the distributed matrix $A$ .                                                                                                                                                                                           |
| <code>work</code> | On exit, <code>work[0]</code> returns the minimal and optimal <code>lwork</code> .                                                                                                                                                                                                                                                                                              |
| <code>info</code> | (local) If <code>info = 0</code> , the execution is successful. If <code>info &lt; 0</code> : If the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then <code>info = -(*100+j)</code> , if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .                                                 |

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$Q = H(ia+k-1)*H(ia+k-2)*\dots*H(ia)$  for real flavors,  $Q = (H(ia+k-1))^H * (H(ia+k-2))^H \dots * (H(ia))^H$  for complex flavors,

where  $k = \min(m, n)$ .

Each  $H(i)$  has the form

$H(i) = I - tau*v*v'$

where `tau` is a real/complex scalar, and `v` is a real/complex vector with  $v(1: i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1: n)$  (for real flavors) or `conjg(v(i+1: n))` (for complex flavors) is stored on exit in  $A(ia+i-1, ja+i: ja+n-1)$ , and `tau` in `tau[ia+i-2]`.

## Description

The p?geql2 function computes a  $QL$  factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * L$ .

## Input Parameters

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <i>work</i>           | (local).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                       | This is a workspace array of size <i>lwork</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>lwork</i>          | (local or global)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                       | The size of the array <i>work</i> .<br><br><i>lwork</i> is local input and must be at least $\text{lwork} \geq mp0 + \max(1, nq0)$ ,<br>where <i>iroff</i> = $\text{mod}(ia-1, mb\_a)$ , <i>icoff</i> = $\text{mod}(ja-1, nb\_a)$ ,<br><i>iarow</i> = $\text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$ ,<br><i>iacol</i> = $\text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol)$ ,<br><i>mp0</i> = $\text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow)$ ,<br><i>nq0</i> = $\text{numroc}(n+icoff, nb\_a, mycol, iacol, npcol)$ ,<br>$\text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the function <i>blacs_gridinfo</i> . |

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

## Output Parameters

- $a$  (local).  
On exit,  
if  $m \geq n$ , the lower triangle of the distributed submatrix  $A(ia+m-n:ia+m-1, ja:ja+n-1)$  contains the  $n$ -by- $n$  lower triangular matrix  $L$ ;  
if  $m \leq n$ , the elements on and below the  $(n-m)$ -th superdiagonal contain the  $m$ -by- $n$  lower trapezoidal matrix  $L$ ; the remaining elements, with the array  $tau$ , represent the orthogonal/ unitary matrix  $Q$  as a product of elementary reflectors (see *Application Notes* below).
- $tau$  (local).  
Array of size  $LOCc(ja+n-1)$ . This array contains the scalar factors of the elementary reflectors.  $tau$  is tied to the distributed matrix  $A$ .
- $work$  On exit,  $work[0]$  returns the minimal and optimal  $lwork$ .
- $info$  (local).  
If  $info = 0$ , the execution is successful. If  $info < 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja), \text{ where } k = \min(m, n).$$

Each  $H(i)$  has the form

$$H(i) = I - tau * v * v'$$

where  $tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(m-k+i+1: m) = 0$  and  $v(m-k+i) = 1$ ;  $v(1: m-k+i-1)$  is stored on exit in  $A(ia:ia+m-k+i-2, ja+n-k+i-1)$ , and  $tau$  in  $tau[ja+n-k+i-2]$ .

## p?geqr2

Computes a QR factorization of a general rectangular matrix (unblocked algorithm).

## Syntax

```
void psgeqr2 (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT
*desca, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);

void pdgeqr2 (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT
*desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
```

```
void pcgeqr2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info);
```

```
void pzgeqr2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info);
```

## Description

The p?geqr2 function computes a QR factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*R$ .

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>      | (global)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|               | The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>n</i>      | (global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>a</i>      | (local).<br>Pointer into the local memory to an array of size $\text{lld}_a * \text{LOC}_c(ja+n-1)$ .<br>On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ which is to be factored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>desca</i>  | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>work</i>   | (local).<br>This is a workspace array of size <i>lwork</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>lwork</i>  | (local or global)<br>The size of the array <i>work</i> .<br><br><i>lwork</i> is local input and must be at least $\text{lwork} \geq \text{mp0} + \max(1, \text{nq0})$ ,<br>where $\text{iroff} = \text{mod}(ia-1, \text{mb\_a})$ , $\text{icoff} = \text{mod}(ja-1, \text{nb\_a})$ ,<br>$\text{iarow} = \text{indxg2p}(ia, \text{mb\_a}, \text{myrow}, \text{rsrc\_a}, \text{nprow})$ ,<br>$\text{iacol} = \text{indxg2p}(ja, \text{nb\_a}, \text{mycol}, \text{csrc\_a}, \text{npcol})$ ,<br>$\text{mp0} = \text{numroc}(m+\text{iroff}, \text{mb\_a}, \text{myrow}, \text{iarow}, \text{nprow})$ ,<br>$\text{nq0} = \text{numroc}(n+\text{icoff}, \text{nb\_a}, \text{mycol}, \text{iacol}, \text{npcol})$ .<br><i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the function <i>blacs_gridinfo</i> . |

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

## Output Parameters

|        |                                                                                                                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $a$    | (local).                                                                                                                                                                                                                                                                                                                                             |
|        | On exit, the elements on and above the diagonal of sub( $A$ ) contain the $\min(m,n)$ by $n$ upper trapezoidal matrix $R$ ( $R$ is upper triangular if $m \geq n$ ); the elements below the diagonal, with the array $tau$ , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below). |
| $tau$  | (local).                                                                                                                                                                                                                                                                                                                                             |
|        | Array of size $LOCc(ja + \min(m,n) - 1)$ . This array contains the scalar factors of the elementary reflectors. $tau$ is tied to the distributed matrix $A$ .                                                                                                                                                                                        |
| $work$ | On exit, $work[0]$ returns the minimal and optimal $lwork$ .                                                                                                                                                                                                                                                                                         |
| $info$ | (local)<br>If $info = 0$ , the execution is successful. If $info < 0$ :<br>If the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then $info = -(i*100+j)$ ,<br>if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .                                                           |

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1), \text{ where } k = \min(m, n).$$

Each  $H(i)$  has the form

$$H(j) = I - tau * v * v^T,$$

where  $tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1:m)$  is stored on exit in  $A(ia+i:ia+m-1, ja+i-1)$ , and  $tau$  in  $tau[ja+i-2]$ .

## Description

The `p?gerq2` function computes an *RQ* factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = R*Q$ .

## Input Parameters

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <code>m</code>      | (global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>n</code>      | (global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>a</code>      | (local).<br>Pointer into the local memory to an array of size $\text{lld}_a * \text{LOC}_c(ja+n-1)$ .<br>On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ which is to be factored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>ia, ja</code> | (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>desca</code>  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>work</code>   | (local).<br>This is a workspace array of size $lwork$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>lwork</code>  | (local or global)<br>The size of the array <code>work</code> .<br><br><code>lwork</code> is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$ , where<br><br><code>iroff = mod(ia-1, mb_a), icooff = mod(ja-1, nb_a),</code><br><code>iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),</code><br><code>iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol), mp0 =</code><br><code>numroc(m+iroff, mb_a, myrow, iarow, nprow),</code><br><code>nq0 = numroc(n+icooff, nb_a, mycol, iacol, npcol),</code><br><code>indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow, and npcol can be determined by calling the function blacs_gridinfo.</code><br><br>If <code>lwork = -1</code> , then <code>lwork</code> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> . |

## Output Parameters

|                |          |
|----------------|----------|
| <code>a</code> | (local). |
|----------------|----------|

On exit,

if  $m \leq n$ , the upper triangle of  $A(ia+m-n:ia+m-1, ja:ja+n-1)$  contains the  $m$ -by- $m$  upper triangular matrix  $R$ ;

if  $m \geq n$ , the elements on and above the  $(m-n)$ -th subdiagonal contain the  $m$ -by- $n$  upper trapezoidal matrix  $R$ ; the remaining elements, with the array  $\tau$ , represent the orthogonal/ unitary matrix  $Q$  as a product of elementary reflectors (see *Application Notes* below).

$\tau$

Array of size  $LOCr(ia+m - 1)$ . This array contains the scalar factors of the elementary reflectors.  $\tau$  is tied to the distributed matrix  $A$ .

$work$

On exit,  $work[0]$  returns the minimal and optimal  $lwork$ .

$info$

(local)

If  $info = 0$ , the execution is successful.

if  $info < 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $info = - (i * 100 + j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1)$  for real flavors,

$Q = (H(ia))^H * (H(ia+1))^H * \dots * (H(ia+k-1))^H$  for complex flavors,

where  $k = \min(m, n)$ .

Each  $H(i)$  has the form

$H(i) = I - \tau v * v^T$ ,

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(n-k+i+1:n) = 0$  and  $v(n-k+i) = 1$ ;  $v(1:n-k+i-1)$  for real flavors or  $\text{conjg}(v(1:n-k+i-1))$  for complex flavors is stored on exit in  $A(ia+m-k+i-1, ja:ja+n-k+i-2)$ , and  $\tau$  in  $\tau[ia+m-k+i-2]$ .

## Description

The `pzgetf2` function computes an *LU* factorization of a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$  using partial pivoting with row interchanges.

The factorization has the form  $\text{sub}(A) = P * L * U$ , where  $P$  is a permutation matrix,  $L$  is lower triangular with unit diagonal elements (lower trapezoidal if  $m > n$ ), and  $U$  is upper triangular (upper trapezoidal if  $m < n$ ). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

### p?labrd

Reduces the first  $nb$  rows and columns of a general rectangular matrix  $A$  to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of  $A$ .

### Description

The `p?labrd` function reduces the first  $nb$  rows and columns of a real/complex general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$  to upper or lower bidiagonal form by an orthogonal/unitary transformation  $Q^* A P$ , and returns the matrices  $X$  and  $Y$  necessary to apply the transformation to the unreduced part of  $\text{sub}(A)$ .

If  $m \geq n$ ,  $\text{sub}(A)$  is reduced to upper bidiagonal form; if  $m < n$ ,  $\text{sub}(A)$  is reduced to lower bidiagonal form.

This is an auxiliary function called by [p?gebrd](#).

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>      | (global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                |
| <i>n</i>      | (global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).                                                                                                                                                                                                                                                                                                                                             |
| <i>nb</i>     | (global)<br>The number of leading rows and columns of $\text{sub}(A)$ to be reduced.                                                                                                                                                                                                                                                                                                                                                   |
| <i>a</i>      | (local).<br>Pointer into the local memory to an array of size $l1d\_a * LOC_c(ja+n-1)$ .<br>On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$ .                                                                                                                                                                                                                                         |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                               |
| <i>descA</i>  | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                  |
| <i>ix, jx</i> | (global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the matrix $\text{sub}(X)$ , respectively.                                                                                                                                                                                                                                                                               |
| <i>descX</i>  | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $X$ .                                                                                                                                                                                                                                                                                                                                  |

| <i>work</i>   | (local).<br>Workspace array of size <i>lwork</i> .<br><br>$lwork \geq nb\_a + nq,$<br>with $nq = \text{numroc}(n+\text{mod}(ia-1, nb\_y), nb\_y, mycol, iacol, npcol)$<br>$iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol)$<br><i>indxg2p</i> and <i>numroc</i> are ScalAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the function <i>blacs_gridinfo</i> . |

## Output Parameters

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i> | (local)<br>On exit, the first <i>nb</i> rows and columns of the matrix are overwritten; the rest of the distributed matrix $\text{sub}(A)$ is unchanged.<br><br>If $m \geq n$ , elements on and below the diagonal in the first <i>nb</i> columns, with the array <i>tauq</i> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors; and elements above the diagonal in the first <i>nb</i> rows, with the array <i>taup</i> , represent the orthogonal/unitary matrix $P$ as a product of elementary reflectors. |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

If  $m < n$ , elements below the diagonal in the first  $nb$  columns, with the array  $\text{tauq}$ , represent the orthogonal/unitary matrix  $Q$  as a product of elementary reflectors, and elements on and above the diagonal in the first  $nb$  rows, with the array  $\text{taup}$ , represent the orthogonal/unitary matrix  $P$  as a product of elementary reflectors. See *Application Notes* below.

*d*

(local).

Array of size  $\text{LOCr}(ia+\min(m,n)-1)$  if  $m \geq n$ ;  $\text{LOCc}(ja+\min(m,n)-1)$  otherwise. The distributed diagonal elements of the bidiagonal distributed matrix  $B$ :

$$d[i] = A(ia+i, ja+i), i=0, 1, \dots, \text{size}(d)-1$$

*d* is tied to the distributed matrix  $A$ .

*e*

(local).

Array of size  $\text{LOCr}(ia+\min(m,n)-1)$  if  $m \geq n$ ;  $\text{LOCc}(ja+\min(m,n)-2)$  otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix  $B$ :

$$\text{if } m \geq n, e[i] = A(ia+i, ja+i+1) \text{ for } i = 0, 1, \dots, n-2;$$

$$\text{if } m < n, e[i] = A(ia+i+1, ja+i) \text{ for } i = 0, 1, \dots, m-2.$$

*e* is tied to the distributed matrix  $A$ .

*tauq, taup*

(local).

Array size  $\text{LOCc}(ja+\min(m,n)-1)$  for  $\text{tauq}$ , size  $\text{LOCr}(ia+\min(m,n)-1)$  for  $\text{taup}$ . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix  $Q$  for  $\text{tauq}$ ,  $P$  for  $\text{taup}$ .  $\text{tauq}$  and  $\text{taup}$  are tied to the distributed matrix  $A$ . See *Application Notes* below.

*x*

(local)

Pointer into the local memory to an array of size  $\text{lld}_x * nb$ . On exit, the local pieces of the distributed  $m$ -by- $nb$  matrix  $X(ix:ix+m-1, jx:jx+nb-1)$  required to update the unreduced part of  $\text{sub}(A)$ .

*y*

(local).

Pointer into the local memory to an array of size  $\text{lld}_y * nb$ . On exit, the local pieces of the distributed  $n$ -by- $nb$  matrix  $Y(iy:iy+n-1, jy:jy+nb-1)$  required to update the unreduced part of  $\text{sub}(A)$ .

## Application Notes

The matrices  $Q$  and  $P$  are represented as products of elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb), \text{ and } P = G(1) * G(2) * \dots * G(nb)$$

Each  $H(i)$  and  $G(i)$  has the form:

$$H(i) = I - \text{tauq} * v * v', \text{ and } G(i) = I - \text{taup} * u * u',$$

where  $\text{tauq}$  and  $\text{taup}$  are real/complex scalars, and  $v$  and  $u$  are real/complex vectors.

If  $m \geq n$ ,  $v(1: i-1) = 0$ ,  $v(i) = 1$ , and  $v(i:m)$  is stored on exit in

$A(ia+i-1:ia+m-1, ja+i-1); u(1:i) = 0$ ,  $u(i+1) = 1$ , and  $u(i+1:n)$  is stored on exit in  $A(ia+i-1, ja+i:ja+n-1)$ ;  $\text{tauq}$  is stored in  $\text{tauq}[ja+i-2]$  and  $\text{taup}$  in  $\text{taup}[ia+i-2]$ .

If  $m < n$ ,  $v(1: i) = 0$ ,  $v(i+1 : ) = 1$ , and  $v(i+1:m)$  is stored on exit in

$A(ia+i+1:ia+m-1, ja+i-1); u(1:i-1) = 0, u(i) = 1$ , and  $u(i:n)$  is stored on exit in  $A(ia+i-1, ja+i:ja+n-1); tauq$  is stored in  $tauq[ja+i-2]$  and  $taup$  in  $taup[ia+i-2]$ . The elements of the vectors  $v$  and  $u$  together form the  $m$ -by- $nb$  matrix  $V$  and the  $nb$ -by- $n$  matrix  $U'$  which are necessary, with  $X$  and  $Y$ , to apply the transformation to the unreduced part of the matrix, using a block update of the form:  $\text{sub}(A) := \text{sub}(A) - V*Y' - X*U'$ . The contents of  $\text{sub}(A)$  on exit are illustrated by the following examples with  $nb = 2$ :

$m = 6$  and  $n = 5(m > n)$ :

$$\begin{bmatrix} 1 & 1 & v_1 & u_1 & u_1 \\ v_1 & 1 & 1 & u_2 & u_2 \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

$m = 5$  and  $n = 6(m < n)$ :

$$\begin{bmatrix} 1 & u_1 & u_1 & u_1 & u_1 & u_1 \\ 1 & 1 & u_2 & u_2 & u_2 & u_2 \\ v_1 & 1 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \end{bmatrix}$$

where  $a$  denotes an element of the original matrix which is unchanged,  $v_i$  denotes an element of the vector defining  $H(i)$ , and  $u_i$  an element of the vector defining  $G(i)$ .

## Description

The `p?lacon` function estimates the 1-norm of a square, real/unitary distributed matrix  $A$ . Reverse communication is used for evaluating matrix-vector products.  $x$  and  $v$  are aligned with the distributed matrix  $A$ , this information is implicitly contained within  $iv$ ,  $ix$ ,  $descv$ , and  $descx$ .

## Input Parameters

|          |                                                                                                                                                                                                                |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $n$      | (global) The length of the distributed vectors $v$ and $x$ . $n \geq 0$ .                                                                                                                                      |
| $v$      | (local).<br>Pointer into the local memory to an array of size $LOCr(n+\text{mod}(iv-1, mb\_v))$ . On the final return, $v = a^*w$ , where $\text{est} = \text{norm}(v)/\text{norm}(w)$ ( $w$ is not returned). |
| $iv, jv$ | (global) The row and column indices in the global matrix $V$ indicating the first row and the first column of the submatrix $V$ , respectively.                                                                |
| $descv$  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $V$ .                                                                                                               |
| $x$      | (local).<br>Pointer into the local memory to an array of size $LOCr(n+\text{mod}(ix-1, mb\_x))$ .                                                                                                              |
| $ix, jx$ | (global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the submatrix $X$ , respectively.                                                                |
| $descx$  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $X$ .                                                                                                               |
| $isgn$   | (local).<br>Array of size $LOCr(n+\text{mod}(ix-1, mb\_x))$ . $isgn$ is aligned with $x$ and $v$ .                                                                                                             |
| $kase$   | (local).<br>On the initial call to <code>p?lacon</code> , $kase$ should be 0.                                                                                                                                  |

## Output Parameters

|        |                                                                                                                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $x$    | (local).<br>On an intermediate return, $X$ should be overwritten by $A^*X$ , if $kase=1$ , $A'^*X$ , if $kase=2$ ,<br><code>p?lacon</code> must be re-called with all the other parameters unchanged. |
| $est$  | (global).                                                                                                                                                                                             |
| $kase$ | (local)<br>On an intermediate return, $kase$ is 1 or 2, indicating whether $X$ should be overwritten by $A^*X$ , or $A'^*X$ . On the final return from <code>p?lacon</code> , $kase$ is again 0.      |

```

**Include Files**

- mkl\_scalapack.h

**Description**

The p?laconsbfunction looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift QR iteration given by  $h44$ ,  $h33$ , and  $h43h34$  to see if this process makes a subdiagonal negligible.

**Input Parameters**

|                                         |                                                                                                                                                                                            |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i>                                | (local)                                                                                                                                                                                    |
|                                         | Array of size $ld\_a * LOCc(n\_a)$ . On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.                                                           |
| <i>desca</i>                            | (global and local)                                                                                                                                                                         |
|                                         | Array of size $dlen_$ . The array descriptor for the distributed matrix <i>A</i> .                                                                                                         |
| <i>i</i>                                | (global)                                                                                                                                                                                   |
|                                         | The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit.                                                                                              |
| <i>l</i>                                | (global)                                                                                                                                                                                   |
|                                         | The global location of the top of the unreduced submatrix of <i>A</i> . Unchanged on exit.                                                                                                 |
| <i>h44</i> , <i>h33</i> , <i>h43h34</i> | (global).                                                                                                                                                                                  |
|                                         | These three values are for the double shift QR iteration.                                                                                                                                  |
| <i>lwork</i>                            | (local)                                                                                                                                                                                    |
|                                         | This must be at least $7 * \text{ceil}(\text{ceil}( (i-1) / mb\_a ) / \text{lcm}(n\_row, n\_col))$ . Here lcm is the least common multiple and $n\_row * n\_col$ is the logical grid size. |

## Output Parameters

*m* (global). On exit, this yields the starting location of the QR double shift.  
This will satisfy:  
 $i \leq m \leq i-2$ .

*buf* (local).  
Array of size *lwork*.

*descb);
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?lacp2` function copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, `p?lacp2` performs a local copy  $\text{sub}(A) := \text{sub}(B)$ , where  $\text{sub}(A)$  denotes  $A(ia:ia+m-1, a:ja+n-1)$  and  $\text{sub}(B)$  denotes  $B(ib:ib+m-1, jb:jb+n-1)$ .

`p?lacp2` requires that only dimension of the matrix operands is distributed.

## Input Parameters

*uplo* (global) Specifies the part of the distributed matrix  $\text{sub}(A)$  to be copied:  
= '`U`': Upper triangular part is copied; the strictly lower triangular part of  $\text{sub}(A)$  is not referenced;  
= '`L`': Lower triangular part is copied; the strictly upper triangular part of  $\text{sub}(A)$  is not referenced.  
Otherwise: all of the matrix  $\text{sub}(A)$  is copied.

*m* (global)  
The number of rows in the distributed matrix  $\text{sub}(A)$ . ( $m \geq 0$ ).

|               |                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>      | (global)<br>The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).                                                                                                                   |
| <i>a</i>      | (local).<br>Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(ja+n-1)$ .<br>On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ . |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.                                                                   |
| <i>desca</i>  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .                                                                                                                |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix $B$ indicating the first row and the first column of $\text{sub}(B)$ , respectively.                                                                   |
| <i>descb</i>  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $B$ .                                                                                                                |

## Output Parameters

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Description

This is an auxiliary function that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

| <i>ldb</i>    | (local)<br>The leading dimension of <i>B</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>ii, jj</i> | (global) By using <i>rev</i> 0 and 1, data can be sent out and returned again. If <i>rev</i> = 0, then <i>ii</i> is destination row index and <i>jj</i> is destination column index for the node(s) receiving the replicated matrix <i>B</i> . If <i>ii</i> ≥ 0, <i>jj</i> ≥ 0, then node ( <i>ii, jj</i> ) receives the data. If <i>ii</i> = -1, <i>jj</i> ≥ 0, then all rows in column <i>jj</i> receive the data. If <i>ii</i> ≥ 0, <i>jj</i> = -1, then all cols in row <i>ii</i> receive the data. If <i>ii</i> = -1, <i>jj</i> = -1, then all nodes receive the data. If <i>rev</i> != 0, then <i>ii</i> is the source row index for the node(s) sending the replicated <i>B</i> . |
| <i>rev</i>    | (global) Use <i>rev</i> = 0 to send global matrix <i>A</i> into locally replicated matrix <i>B</i> (on node ( <i>ii, jj</i> )). Use <i>rev</i> != 0 to send locally replicated <i>B</i> from node ( <i>ii, jj</i> ) to its owner (which changes depending on its location in <i>A</i> ) into the global <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                       |

## Output Parameters

- a*                    On exit, if *rev* = 1, the copied data. Unchanged on exit if *rev* = 0.  
*b*                    If *rev* = 1, this is unchanged on exit.

## p?lacpy

*Copies all or part of one two-dimensional array to another.*

## Syntax

```
void pslacpy (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
 *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb);
void pdlacpy (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
 *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb);
void pclacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*descb);
void pzlacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*descb);
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lacpy function copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, p?lacpy performs a local copy *sub(B):= sub(A)*, where *sub(A)* denotes *A(ia:ia+m-1, ja:ja+n-1)* and *sub(B)* denotes *B(ib:ib+m-1, jb:jb+n-1)*.

## Input Parameters

- uplo*                    (global) Specifies the part of the distributed matrix *sub(A)* to be copied:  
= 'U': Upper triangular part; the strictly lower triangular part of *sub(A)* is not referenced;  
= 'L': Lower triangular part; the strictly upper triangular part of *sub(A)* is not referenced.  
Otherwise: all of the matrix *sub(A)* is copied.
- m*                    (global)  
The number of rows in the distributed matrix *sub(A)*. (*m*≥0).
- n*                    (global)  
The number of columns in the distributed matrix *sub(A)*. (*n*≥0).
- a*                    (local).  
Pointer into the local memory to an array of size *l1d\_a \* LOCc(ja+n-1)*.

On entry, this array contains the local pieces of the distributed matrix  $\text{sub}(A)$ .

|          |                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| $ia, ja$ | (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively. |
| $desca$  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .                                                         |
| $ib, jb$ | (global) The row and column indices in the global matrix $B$ indicating the first row and the first column of $\text{sub}(B)$ respectively.              |
| $descb$  | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $B$ .                                                         |

## Output Parameters

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $b$ | (local).<br>Pointer into the local memory to an array of size $lld\_b * LOCc(jb+n-1)$ . This array contains on exit the local pieces of the distributed matrix $\text{sub}(B)$ set as follows:<br><br>if $uplo = 'U'$ , $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $1 \leq i \leq j$ , $1 \leq j \leq n$ ;<br>if $uplo = 'L'$ , $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $j \leq i \leq m$ , $1 \leq j \leq n$ ;<br>otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $1 \leq i \leq m$ , $1 \leq j \leq n$ . |

## p?laevswp

*Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.*

## Syntax

```
void pslaevswp (MKL_INT *n , float *zin , MKL_INT *ldzi , float *z , MKL_INT *iz ,
MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *work , MKL_INT
*lwork);

void pdlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , double *z , MKL_INT *iz ,
MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *work , MKL_INT
*lwork);

void pclaeve (MKL_INT *n , float *zin , MKL_INT *ldzi , MKL_Complex8 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *rwork ,
MKL_INT *lrwork);

void pzlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , MKL_Complex16 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *rwork ,
MKL_INT *lrwork);
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?laevswp` function moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

## Input Parameters

`np` = the number of rows local to a given process.

`nq` = the number of columns local to a given process.

`n` (global)

The order of the matrix  $A$ .  $n \geq 0$ .

`zin` (local).

Array of size  $ldzi * nvs[iam+1]$ . The eigenvectors on input.  $iam$  is a process rank from  $[0, nprocs)$  interval. Each eigenvector resides entirely in one process. Each process holds a contiguous set of  $nvs[iam+1]$  eigenvectors. The global number of the first eigenvector that the process holds is: ((sum for  $i=[0, iam]$  of  $nvs[i]$ )+1).

`ldzi` (local)

The leading dimension of the `zin` array.

`iz, jz` (global) The row and column indices in the global matrix  $Z$  indicating the first row and the first column of the submatrix  $Z$ , respectively.

`descz` (global and local)

Array of size `dlen_`. The array descriptor for the distributed matrix  $Z$ .

`nvs` (global)

Array of size `nprocs+1`

$nvs[i] =$  number of eigenvectors held by processes  $[0, i)$

$nvs[0] =$  number of eigenvectors held by processes  $[0, 0) = 0$

$nvs[nprocs] =$  number of eigenvectors held by  $[0, nprocs) =$  total number of eigenvectors.

`key` (global)

Array of size  $n$ . Indicates the actual index (after sorting) for each of the eigenvectors.

`rwork` (local).

Array of size `lrwork`.

`lrwork` (local)

Size of `work`.

## Output Parameters

`z` (local).

Array of global size  $n * n$  and of local size  $ld_z * nq$ . The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of  $nb$ .

### p?lahrd

*Reduces the first nb columns of a general rectangular matrix A so that elements below the k-th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.*

### Syntax

```
void pslahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *t , float *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , float *work);

void pdlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *t , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , double *work);

void pclahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *t , MKL_Complex8 *y ,
MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex8 *work);

void pzlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *t , MKL_Complex16
*y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex16 *work);
```

### Include Files

- mkl\_scalapack.h

### Description

The p?lahrd function reduces the first nb columns of a real general n-by-(n-k+1) distributed matrix  $A(ia:ia+n-1, ja:ja+n-k)$  so that elements below the k-th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation  $Q^*A^*Q$ . The function returns the matrices V and T which determine Q as a block reflector  $I-V^*T^*V'$ , and also the matrix Y =  $A^*V^*T$ .

This is an auxiliary function called by p?gehrd. In the following comments sub(A) denotes  $A(ia:ia+n-1, ja:ja+n-1)$ .

### Input Parameters

|    |                                                                                                                |
|----|----------------------------------------------------------------------------------------------------------------|
| n  | (global)                                                                                                       |
|    | The order of the distributed matrix sub(A). $n \geq 0$ .                                                       |
| k  | (global)                                                                                                       |
|    | The offset for the reduction. Elements below the k-th subdiagonal in the first nb columns are reduced to zero. |
| nb | (global)                                                                                                       |
|    | The number of columns to be reduced.                                                                           |
| a  | (local).                                                                                                       |

Pointer into the local memory to an array of size  $\text{lld}_a * \text{LOCc}(ja+n-k)$ . On entry, this array contains the local pieces of the  $n$ -by- $(n-k+1)$  general distributed matrix  $A(ia:ia+n-1, ja:ja+n-k)$ .

*ia, ja*  
(global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the matrix  $\text{sub}(A)$ , respectively.

*desca*  
(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

*iY, jY*  
(global) The row and column indices in the global matrix  $Y$  indicating the first row and the first column of the matrix  $\text{sub}(Y)$ , respectively.

*descy*  
(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $Y$ .

*work*  
(local).

Array of size  $nb$ .

## Output Parameters

*a*  
(local).

On exit, the elements on and above the  $k$ -th subdiagonal in the first  $nb$  columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the  $k$ -th subdiagonal, with the array *tau*, represent the matrix  $Q$  as a product of elementary reflectors. The other columns of the matrix  $A(ia:ia+n-1, ja:ja+n-k)$  are unchanged. (See *Application Notes* below.)

*tau*  
(local)

Array of size  $\text{LOCc}(ja+n-2)$ . The scalar factors of the elementary reflectors (see *Application Notes* below). *tau* is tied to the distributed matrix  $A$ .

*t*  
(local)

Array of size  $nb\_a * nb\_a$ . The upper triangular matrix  $T$ .

*y*  
(local).

Pointer into the local memory to an array of size  $\text{lld}_y * nb\_a$ . On exit, this array contains the local pieces of the  $n$ -by- $nb$  distributed matrix  $Y$ .  $\text{lld}_y \geq \text{LOCr}(ia+n-1)$ .

## Application Notes

The matrix  $Q$  is represented as a product of  $nb$  elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb).$$

Each  $H(i)$  has the form

$$H(i) = i - tau * v * v^T,$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with  $v(1: i+k-1) = 0$ ,  $v(i+k) = 1$ ;  $v(i+k+1:n)$  is stored on exit in  $A(ia+i+k:ia+n-1, ja+i-1)$ , and *tau* in  $\text{tau}[ja+i-2]$ .

The elements of the vectors  $v$  together form the  $(n-k+1)$ -by- $nb$  matrix  $V$  which is needed, with  $T$  and  $Y$ , to apply the transformation to the unreduced part of the matrix, using an update of the form:  $A(ia:ia+n-1, ja:ja+n-k) := (I-V^*T^*V)^*(A(ia:ia+n-1, ja:ja+n-k)-Y^*V)$ . The contents of  $A(ia:ia+n-1, ja:ja+n-k)$  on exit are illustrated by the following example with  $n = 7$ ,  $k = 3$ , and  $nb = 2$ :

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v1 & h & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

where  $a$  denotes an element of the original matrix  $A(ia:ia+n-1, ja:ja+n-k)$ ,  $h$  denotes a modified element of the upper Hessenberg matrix  $H$ , and  $vi$  denotes an element of the vector defining  $H(i)$ .

## p?laiect

*Exploits IEEE arithmetic to accelerate the computations of eigenvalues.*

---

## Syntax

```
void psblaiect (float *sigma , MKL_INT *n , float *d , MKL_INT *count);
void pdblaiectb (float *sigma , MKL_INT *n , float *d , MKL_INT *count);
void pdblaiectl (float *sigma , MKL_INT *n , float *d , MKL_INT *count);
```

## Include Files

- mkl\_scalapack.h

## Description

The p?laiect function computes the number of negative eigenvalues of  $(A - \sigma I)$ . This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real function psblaiect is assumed to be bit 32. Double-precision functions pdblaiectb and pdblaiectl differ in the order of the double precision word storage and, consequently, in the signbit location. For pdblaiectb, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For pdblaiectl, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

## Input Parameters

*sigma*

The shift. p?laiect finds the number of eigenvalues less than equal to *sigma*.

*n*The order of the tridiagonal matrix  $T$ .  $n \geq 1$ .*d*Array of size  $2n-1$ .

On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix  $T$ . These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of  $T$  are in the entries  $d[0], d[2], \dots, d[2n-2]$ , while the squares of the off-diagonal entries are  $d[1], d[3], \dots, d[2n-3]$ . To avoid overflow, the matrix must be scaled so that its largest entry is no greater than  $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$  in absolute value, and for greatest accuracy, it should not be much smaller than that.

## Output Parameters

*n*The count of the number of eigenvalues of  $T$  less than or equal to  $\sigma$ .

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lamve

Copies all or part of one two-dimensional distributed array to another.

## Syntax

```
void pslamve(char* uplo, MKL_INT* m, MKL_INT* n, float* a, MKL_INT* ia, MKL_INT* ja,
 MKL_INT* desca, float* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, float* dwork);
void pdlamve(char* uplo, MKL_INT* m, MKL_INT* n, double* a, MKL_INT* ia, MKL_INT* ja,
 MKL_INT* desca, double* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, double* dwork);
```

## Include Files

- mkl\_scalapack.h

## Description

p?lamve copies all or part of a distributed matrix  $A$  to another distributed matrix  $B$ . There is no alignment assumptions at all except that  $A$  and  $B$  are of the same size.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

*uplo*

(global )

Specifies the part of the distributed matrix sub(  $A$  ) to be copied:

- = 'U': Upper triangular part is copied; the strictly lower triangular part of sub(  $A$  ) is not referenced;

- = 'L': Lower triangular part is copied; the strictly upper triangular part of sub(  $A$  ) is not referenced;

Otherwise: All of the matrix sub(  $A$  ) is copied.

$m$

(global )

The number of rows to be operated on, which is the number of rows of the distributed matrix sub(  $A$  ).  $m \geq 0$ .

$n$

(global )

The number of columns to be operated on, which is the number of columns of the distributed matrix sub(  $A$  ).  $n \geq 0$ .

$a$

(local ) pointer into the local memory to an array of size  $lId_a * LOC_c(ja + n - 1)$ . This array contains the local pieces of the distributed matrix sub(  $A$  ) to be copied from.

$ia$

(global )

The row index in the global matrix  $A$  indicating the first row of sub(  $A$  ).

$ja$

(global )

The column index in the global matrix  $A$  indicating the first column of sub(  $A$  ).

$desca$

(global and local) array of size  $dlen_$ .

The array descriptor for the distributed matrix  $A$ .

$ib$

(global )

The row index in the global matrix  $B$  indicating the first row of sub(  $B$  ).

$jb$

(global )

The column index in the global matrix  $B$  indicating the first column of sub(  $B$  ).

$descb$

(global and local) array of size  $dlen_$ .

The array descriptor for the distributed matrix  $B$ .

$dwork$

(local workspace) array

If  $uplo = 'U'$  or  $uplo = 'L'$  and number of processors > 1, the length of  $dwork$  is at least as large as the length of  $b$ .

Otherwise,  $dwork$  is not referenced.

## OUTPUT Parameters

$b$

(local ) pointer into the local memory to an array of size  $lId_b * LOC_c(jb + n - 1)$ . This array contains on exit the local pieces of the distributed matrix sub(  $B$  ).

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.

## Syntax

```

float pslange (char *norm , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *work);

double pdlange (char *norm , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *work);

float pclange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work);

double pzlange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,

## Description

The `p?lange` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ .

## Input Parameters

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>norm</code>   | (global) Specifies what value is returned by the function:<br>$= 'M'$ or ' <code>m</code> ': $\text{val} = \max(\text{abs}(A_{ij}))$ , largest absolute value of the matrix $A$ , it's not a matrix norm.<br>$= '1'$ or ' <code>O</code> ' or ' <code>o</code> ': $\text{val} = \text{norm1}(A)$ , 1-norm of the matrix $A$ (maximum column sum),<br>$= 'I'$ or ' <code>i</code> ': $\text{val} = \text{normI}(A)$ , infinity norm of the matrix $A$ (maximum row sum),<br>$= 'F'$ , ' <code>f</code> ', ' <code>E</code> ' or ' <code>e</code> ': $\text{val} = \text{normF}(A)$ , Frobenius norm of the matrix $A$ (square root of sum of squares). |

## p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

## Syntax

```
float pslanhs (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *work);

double pdlanhs (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *work);

float pclanh (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *work);

double pzlanhs (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *work);
```

## Include Files

## Description

The p?lanhsfunction returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ .

## Input Parameters

|             |                                                     |
|-------------|-----------------------------------------------------|
| <i>norm</i> | Specifies the value to be returned by the function: |
|-------------|-----------------------------------------------------|

= 'M' or 'm':  $val = \max(|A_{ij}|)$ , largest absolute value of the matrix A.

= '1' or 'O' or 'o':  $val = \text{norm1}(A)$ , 1-norm of the matrix A (maximum column sum),

= 'I' or 'i':  $val = \text{normI}(A)$ , infinity norm of the matrix A (maximum row sum),

= 'F', 'f', 'E' or 'e':  $val = \text{normF}(A)$ , Frobenius norm of the matrix A (square root of sum of squares).

*n*

(global)  
The number of columns in the distributed matrix  $\text{sub}(A)$ . When  $n = 0$ ,  $p\text{?lanhs}$  is set to zero.  $n \geq 0$ .

*a*

(local).  
Pointer into the local memory to an array of size  $lld\_a * LOCc(ja+n-1)$  containing the local pieces of the distributed matrix  $\text{sub}(A)$ .

*ia, ja*

(global)  
The row and column indices in the global matrix  $A$  indicating the first row and the first column of the matrix  $\text{sub}(A)$ , respectively.

*desca*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

*work*

(local).

Array of size  $lwork$ .

$lwork \geq 0$  if  $norm = 'M'$  or ' $m$ ' (not referenced),

$nq0$  if  $norm = '1'$ , ' $O$ ' or ' $o$ ',

$mp0$  if  $norm = 'I'$  or ' $i$ ',

0 if  $norm = 'F'$ , ' $f$ ', ' $E$ ' or ' $e$ ' (not referenced),

where

$iroffa = \text{mod}(ia-1, mb\_a)$ ,  $icoffa = \text{mod}(ja-1, nb\_a)$ ,

$iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$ ,

$iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol)$ ,

$mp0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow)$ ,

$nq0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcol)$ ,

$\text{indxg2p}$  and  $\text{numroc}$  are ScaLAPACK tool functions;  $myrow$ ,  $imycol$ ,  $nprow$ , and  $npcol$  can be determined by calling the function  $\text{blacs\_gridinfo}$ .

## Output Parameters

*val*

The value returned by the function.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

### Syntax

```
float pslansy (char *norm , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *work);

double pdlansy (char *norm , char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *work);

float pclansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work);

double pzlansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work);

float pclanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work);

double pzlanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work);
```

### Description

The `p?lansy` and `p?lanhe` functions return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix `sub(A) = A(ia:ia+m-1, ja:ja+n-1)`.

### Input Parameters

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>norm</code> | (global) Specifies what value is returned by the function:<br><br>= 'M' or 'm': <code>val = max(abs(A<sub>ij</sub>))</code> , largest absolute value of the matrix <code>A</code> , it's not a matrix norm.<br><br>= '1' or 'O' or 'o': <code>val = norm1(A)</code> , 1-norm of the matrix <code>A</code> (maximum column sum),<br><br>= 'I' or 'i': <code>val = normI(A)</code> , infinity norm of the matrix <code>A</code> (maximum row sum),<br><br>= 'F', 'f', 'E' or 'e': <code>val = normF(A)</code> , Frobenius norm of the matrix <code>A</code> (square root of sum of squares). |
| <code>uplo</code> | (global) Specifies whether the upper or lower triangular part of the symmetric matrix <code>sub(A)</code> is to be referenced.<br><br>= 'U': Upper triangular part of <code>sub(A)</code> is referenced,<br>= 'L': Lower triangular part of <code>sub(A)</code> is referenced.                                                                                                                                                                                                                                                                                                             |
| <code>n</code>    | (global)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The number of columns in the distributed matrix  $\text{sub}(A)$ . When  $n = 0$ ,  $\text{p?lansy}$  is set to zero.  $n \geq 0$ .

*a* (local).

Pointer into the local memory to an array of size  $lld_a * \text{LOCc}(ja+n-1)$  containing the local pieces of the distributed matrix  $\text{sub}(A)$ .

If  $\text{uplo} = 'U'$ , the leading  $n$ -by- $n$  upper triangular part of  $\text{sub}(A)$  contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If  $\text{uplo} = 'L'$ , the leading  $n$ -by- $n$  lower triangular part of  $\text{sub}(A)$  contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of  $\text{sub}(A)$  is not referenced.

*ia, ja* (global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the matrix  $\text{sub}(A)$ , respectively.

*desca* (global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

*work* (local).

Array of size  $lwork$ .

$lwork \geq 0$  if  $\text{norm} = 'M'$  or ' $m$ ' (not referenced),  
 $2 * nq0 + mp0 + ldw$  if  $\text{norm} = '1'$ , ' $O$ ' or ' $o$ ', ' $I$ ' or ' $i$ ',

where  $ldw$  is given by:

```
if(nprow!=npcol) then
 ldw = mb_a*iceil(ceil(np0,mb_a),(lcm/nprow))
else
 ldw = 0
end if
```

0 if  $\text{norm} = 'F'$ , ' $f$ ', ' $E$ ' or ' $e$ ' (not referenced),

where  $lcm$  is the least common multiple of  $nprow$  and  $npcol$ ,  $lcm = \text{ilcm}(nprow, nprow)$  and  $\text{ceil}(x, y)$  is a ScaLAPACK function that returns ceiling  $(x/y)$ .

$iroffa = \text{mod}(ia-1, mb_a)$ ,  $icoffa = \text{mod}(ja-1, nb_a)$ ,

$iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$ ,

$iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, nprow)$ ,

$mp0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow)$ ,

$nq0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, nprow)$ ,

$\text{ilcm}$ ,  $\text{ceil}$ ,  $\text{indxg2p}$ , and  $\text{numroc}$  are ScaLAPACK tool functions;  $myrow$ ,  $mycol$ ,  $nprow$ , and  $nprow$  can be determined by calling the function  $\text{blacs_gridinfo}$ .

## Output Parameters

*val*

The value returned by the function.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

### p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

---

### Syntax

```
float pslantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work);
double pdlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work);
float pclantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work);
double pzlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work);
```

### Include Files

- mkl\_scalapack.h

### Description

The `p?lantr` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ .

### Input Parameters

*norm*

(global) Specifies what value is returned by the function:

= 'M' or 'm':  $\text{val} = \max(\text{abs}(A_{ij}))$ , largest absolute value of the matrix  $A$ , it's not a matrix norm.  
= '1' or 'O' or 'o':  $\text{val} = \text{norm1}(A)$ , 1-norm of the matrix  $A$  (maximum column sum),  
= 'I' or 'i':  $\text{val} = \text{normI}(A)$ , infinity norm of the matrix  $A$  (maximum row sum),  
= 'F', 'f', 'E' or 'e':  $\text{val} = \text{normF}(A)$ , Frobenius norm of the matrix  $A$  (square root of sum of squares).

*uplo*

(global)

Specifies whether the upper or lower triangular part of the symmetric matrix  $\text{sub}(A)$  is to be referenced.

= 'U': Upper trapezoidal,  
= 'L': Lower trapezoidal.

Note that  $\text{sub}(A)$  is triangular instead of trapezoidal if  $m = n$ .

*diag*

(global)

Specifies whether the distributed matrix  $\text{sub}(A)$  has unit diagonal.

= 'N': Non-unit diagonal.

= 'U': Unit diagonal.

*m*

(global)

The number of rows in the distributed matrix sub(*A*). When *m* = 0, p?lantr is set to zero. *m* ≥ 0.

*n*

(global)

The number of columns in the distributed matrix sub(*A*). When *n* = 0, p?lantr is set to zero. *n* ≥ 0.

*a*

(local).

Pointer into the local memory to an array of size *lld\_a* \* *LOCc(ja+n-1)* containing the local pieces of the distributed matrix sub(*A*).

*ia*, *ja*

(global)

The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

*desca*

(global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

*work*

(local).

Array size *lwork*.

*lwork* ≥ 0 if *norm* = 'M' or 'm' (not referenced),

*nq0* if *norm* = '1', 'O' or 'o',

*mp0* if *norm* = 'I' or 'i',

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),

*iroffa* = mod(*ia*-1, *mb\_a*), *icoffa* = mod(*ja*-1, *nb\_a*),

*iarow* = indxg2p(*ia*, *mb\_a*, *myrow*, *rsrc\_a*, *nprov*),

*iacol* = indxg2p(*ja*, *nb\_a*, *mycol*, *csrc\_a*, *npcol*),

*mp0* = numroc(*m+iroffa*, *mb\_a*, *myrow*, *iarow*, *nprov*),

*nq0* = numroc(*n+icoffa*, *nb\_a*, *mycol*, *iacol*, *npcol*),

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprov*, and *npcol* can be determined by calling the function blacs\_gridinfo.

## Output Parameters

*val*

The value returned by the function.

## See Also

## p?lapiv

Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.

## Syntax

```
void pslapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *ip ,
MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork);
void pdlapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *ip ,
MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork);
void pclapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT
*ip , MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork);
void pzlapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT
*ip , MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lapiv` function applies either  $P$  (permutation matrix indicated by `ipiv`) or  $\text{inv}(P)$  to a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ , resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix  $A$ . This function will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of  $\text{sub}(A)$ , pass `rowcol='C'` and `pivroc='C'`.

## Input Parameters

|                     |                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>direc</code>  | (global)                                                                                                                   |
|                     | Specifies in which order the permutation is applied:                                                                       |
|                     | = ' <code>F</code> ' (Forward): Applies pivots forward from top of matrix. Computes $P^* \text{sub}(A)$ .                  |
|                     | = ' <code>B</code> ' (Backward): Applies pivots backward from bottom of matrix. Computes $\text{inv}(P)^* \text{sub}(A)$ . |
| <code>rowcol</code> | (global)                                                                                                                   |
|                     | Specifies if the rows or columns are to be permuted:                                                                       |
|                     | = ' <code>R</code>                                                                                                         |
|                     | = ' <code>C</code>                                                                                                         |
| <code>pivroc</code> | (global)                                                                                                                   |
|                     | Specifies whether <code>ipiv</code> is distributed over a process row or column:                                           |
|                     | = ' <code>Ripiv</code> is distributed over a process row,                                                                  |
|                     | = ' <code>Cipiv</code> is distributed over a process column.                                                               |
| <code>m</code>      | (global)                                                                                                                   |

The number of rows in the distributed matrix  $\text{sub}(A)$ . When  $m = 0$ ,  $\text{p?lapiv}$  is set to zero.  $m \geq 0$ .

*n*

(global)

The number of columns in the distributed matrix  $\text{sub}(A)$ . When  $n = 0$ ,  $\text{p?lapiv}$  is set to zero.  $n \geq 0$ .

*a*

(local).

Pointer into the local memory to an array of size  $\text{lld}_a * \text{LOCc}(ja+n-1)$  containing the local pieces of the distributed matrix  $\text{sub}(A)$ .

*ia, ja*

The row and column indices in the global matrix  $A$  indicating the first row and the first column of the matrix  $\text{sub}(A)$ , respectively.

*desca*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

*ipiv*

(local)

Array of size  $lipiv$  ;

when  $\text{rowcol}='R'$  or ' $r$ ' :

$lipiv \geq \text{LOCr}(ia+m-1) + mb\_a$  if  $\text{pivroc}='C'$  or ' $c$ ',

$lipiv \geq \text{LOCc}(m + \text{mod}(jp-1, nb\_p))$  if  $\text{pivroc}='R'$  or ' $r$ ', and,

when  $\text{rowcol}='C'$  or ' $c$ ' :

$lipiv \geq \text{LOCr}(n + \text{mod}(ip-1, mb\_p))$  if  $\text{pivroc}='C'$  or ' $c$ ',

$lipiv \geq \text{LOCc}(ja+n-1) + nb\_a$  if  $\text{pivroc}='R'$  or ' $r$ '.

This array contains the pivoting information.  $ipiv(i)$  is the global row (column), local row (column)  $i$  was swapped with. When  $\text{rowcol}='R'$  or ' $r$ ' and  $\text{pivroc}='C'$  or ' $c$ ', or  $\text{rowcol}='C'$  or ' $c$ ' and  $\text{pivroc}='R'$  or ' $r$ ', the last piece of this array of size  $mb\_a$  (resp.  $nb\_a$ ) is used as workspace. In those cases, this array is tied to the distributed matrix  $A$ .

*ip, jp*

(global) The row and column indices in the global matrix  $P$  indicating the first row and the first column of the matrix  $\text{sub}(P)$ , respectively.

*descip*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed vector  $ipiv$ .

*iwork*

(local).

Array of size  $ldw$ , where  $ldw$  is equal to the workspace necessary for transposition, and the storage of the transposed  $ipiv$ :

Let  $lcm$  be the least common multiple of  $nprow$  and  $npcol$ .

```
if(*rowcol == 'r' && *pivroc == 'r') {
 if(nprow == npcol) {
 ldw = LOCr(n_p + (*jp-1)%nb_p) + nb_p;
 } else {
 ldw = LOCr(n_p + (*jp-1)%nb_p) +
 nb_p * ceil(ceil(LOCc(n_p)/nb_p) / (lcm/npcol));
 }
}
```

```

} else if(*rowcol == 'c' && *pivroc == 'c') {
 if(nprow == npcol) {
 ldw = LOCc(m_p + (*ip-1)%mb_p) + mb_p;
 } else {
 ldw = LOCc(m_p + (*ip-1)%mb_p) +
 mb_p *ceil(ceil(LOCr(m_p)/mb_p) / (lcm/nprow));
 }
} else {
 // iwork is not referenced.
}

```

## Output Parameters

*a* (local).

On exit, the local pieces of the permuted distributed submatrix.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lapv2

Applies a permutation to an *m*-by-*n* distributed matrix.

## Syntax

```

void pslapv2 (const char* direc, const char* rowcol, const MKL_INT* m, const MKL_INT* n, float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);

void pdlapv2 (const char* direc, const char* rowcol, const MKL_INT* m, const MKL_INT* n, double* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);

void pclapv2 (const char* direc, const char* rowcol, const MKL_INT* m, const MKL_INT* n, MKL_Complex8* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);

void pzlapv2 (const char* direc, const char* rowcol, const MKL_INT* m, const MKL_INT* n, MKL_Complex16* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);

```

## Include Files

- mkl\_scalapack.h

## Description

p?lapv2 applies either  $P$  (permutation matrix indicated by *ipiv*) or  $\text{inv}(P)$  to an *m*-by-*n* distributed matrix sub( *A* ) denoting  $A_{(ia:ia+m-1,ja:ja+n-1)}$ , resulting in row or column pivoting. The pivot vector should be aligned with the distributed matrix *A*. For pivoting the rows of sub( *A* ), *ipiv* should be distributed along a process column and replicated over all process rows. Similarly, *ipiv* should be distributed along a process row and replicated over all process columns for column pivoting.

## Input Parameters

*direc* (global)

Specifies in which order the permutation is applied:

= 'F' (Forward) Applies pivots Forward from top of matrix. Computes  $P * \text{sub}(A)$ ;

= 'B' (Backward) Applies pivots Backward from bottom of matrix. Computes  $\text{inv}(P) * \text{sub}(A)$ .

*rowcol*

Specifies if the rows or columns are to be permuted:

= 'R' Rows will be permuted,

= 'C' Columns will be permuted.

*m*

The number of rows to be operated on, i.e. the number of rows of the distributed submatrix  $\text{sub}(A)$ .  $m \geq 0$ .

*n*

The number of columns to be operated on, i.e. the number of columns of the distributed submatrix  $\text{sub}(A)$ .  $n \geq 0$ .

*a*

Pointer into local memory to an array of size  $\text{ld\_a} * \text{LOCc}(ja+n-1)$ .

On entry, this local array contains the local pieces of the distributed matrix  $\text{sub}(A)$  to which the row or columns interchanges will be applied.

*ia*

The row index in the global array *a* indicating the first row of  $\text{sub}(A)$ .

*ja*

The column index in the global array *a* indicating the first column of  $\text{sub}(A)$ .

*desca*

(global and local)

Array of size *dlen\_*.

The array descriptor for the distributed matrix *A*.

*ipiv*

Array, size  $\geq \text{LOCr}(m\_a) + mb\_a$  if *rowcol* = 'R',  $\text{LOCc}(n\_a) + nb\_a$  otherwise.

It contains the pivoting information. *ipiv*[*i* - 1] is the global row (column), local row (column) *i* was swapped with. The last piece of the array of size *mb\_a* or *nb\_a* is used as workspace. *ipiv* is tied to the distributed matrix *A*.

*ip*

The global row index of *ipiv*, which points to the beginning of the submatrix on which to operate.

*jp*

The global column index of *ipiv*, which points to the beginning of the submatrix on which to operate.

*descip*

(global and local)

Array of size 8.

The array descriptor for the distributed matrix *ipiv*.

## Output Parameters

- a* On exit, this array contains the local pieces of the permuted distributed matrix.

## p?laqge

*Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.*

---

## Syntax

```
void pslaqge (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT

## Description

The p?laqge function equilibrates a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$  using the row and scaling factors in the vectors *r* and *c* computed by p?geequ.

## Input Parameters

- m* (global)  
The number of rows in the distributed matrix  $\text{sub}(A)$ . ( $m \geq 0$ ).
- n* (global)  
The number of columns in the distributed matrix  $\text{sub}(A)$ . ( $n \geq 0$ ).
- a* (local).  
Pointer into the local memory to an array of size  $l1d\_a * \text{LOCc}(ja+n-1)$ .  
On entry, this array contains the distributed matrix  $\text{sub}(A)$ .
- ia, ja* (global) The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix  $\text{sub}(A)$ , respectively.
- desca* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

---

|               |                                                                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>r</i>      | (local).                                                                                                                                                                                                                                      |
|               | Array of size $\text{LOC}_r(m\_a)$ . The row scale factors for $\text{sub}(A)$ . <i>r</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>r</i> is tied to the distributed matrix <i>A</i> . |
| <i>c</i>      | (local).                                                                                                                                                                                                                                      |
|               | Array of size $\text{LOC}_c(n\_a)$ . The row scale factors for $\text{sub}(A)$ . <i>c</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>c</i> is tied to the distributed matrix <i>A</i> . |
| <i>rowcnd</i> | (local).                                                                                                                                                                                                                                      |
|               | The global ratio of the smallest $r[i]$ to the largest $r[i]$ , $ia-1 \leq i \leq ia+m-2$ .                                                                                                                                                   |

## Description

p?laqr0 computes the eigenvalues of a Hessenberg matrix  $H$  and, optionally, the matrices  $T$  and  $Z$  from the Schur decomposition  $H = Z*T*Z^T$ , where  $T$  is an upper quasi-triangular matrix (the Schur form), and  $Z$  is the orthogonal matrix of Schur vectors.

Optionally  $Z$  may be postmultiplied into an input orthogonal matrix  $Q$  so that this function can give the Schur factorization of a matrix  $A$  which has been reduced to the Hessenberg form  $H$  by the orthogonal matrix  $Q$ :  $A = Q * H * Q^T = (QZ) * T * (QZ)^T$ .

## Input Parameters

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| wantt      | (global )                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## OUTPUT Parameters

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>h</code>        | On exit, if <code>wantt</code> is non-zero, the matrix <code>H</code> is upper quasi-triangular in rows and columns <code>ilo:ih</code> , with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i)*H(i,i+1) < 0$ . If <code>info</code> = 0 and <code>wantt</code> equals zero, the contents of <code>h</code> are unspecified on exit.                                                                                                           |
| <code>wr, wi</code>   | The real and imaginary parts, respectively, of the computed eigenvalues <code>ilo</code> to <code>ih</code> are stored in the corresponding elements of <code>wr</code> and <code>wi</code> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <code>wr</code> and <code>wi</code> , say the <i>i</i> -th and ( <i>i</i> +1)th, with <code>wi[i-1] &gt; 0</code> and <code>wi[i] &lt; 0</code> . If <code>wantt</code> is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <code>h</code> . |
| <code>z</code>        | Updated matrix with transformations applied only to the submatrix $Z(ilo:ih,ilo:ih)$ .<br><br>If <code>COMPZ</code> = 'I', on exit, if <code>info</code> = 0, <code>z</code> contains the orthogonal matrix <code>Z</code> of the Schur vectors of <code>H</code> .<br><br>If <code>wantz</code> is non-zero, then $Z(ilo:ih,ilo:ih)$ is replaced by $Z(ilo:ih,ilo:ih)*U$ , when <code>U</code> is the orthogonal/unitary Schur factor of $H(ilo:ih,ilo:ih)$ .<br><br>If <code>wantz</code> equals zero, then <code>z</code> is not defined.                                                              |
| <code>work[0]</code>  | On exit, if <code>info</code> = 0, <code>work[0]</code> returns the optimal <code>lwork</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>iwork[0]</code> | On exit, if <code>info</code> = 0, <code>iwork[0]</code> returns the optimal <code>liwork</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>info</code>     | > 0: if <code>info</code> = <i>i</i> , then the function failed to compute all the eigenvalues.<br>Elements <code>0:ilo-2</code> and <code>i:n-1</code> of <code>wr</code> and <code>wi</code> contain those eigenvalues which have been successfully computed.                                                                                                                                                                                                                                                                                                                                           |

> 0: if `wantt`equals zero, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns `ilo` through `ihi` of the final output value of *H*.

> 0: if `wantt` is non-zero, then (initial value of *H*)\**U* = *U*\*(final value of *H*), where *U* is an orthogonal/unitary matrix. The final value of *H* is upper Hessenberg and quasi-triangular/triangular in rows and columns `info+1` through `ihi`.

> 0: if `wantz` is non-zero, then (final value of *Z*(`ilo:ihi,iloz:ihiz`))=(initial value of *Z*(`ilo:ihi,iloz:ihiz`))\**U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of `wantt`).

> 0: if `wantz`equals zero, then *z* is not accessed.

### Description

`p?laqr1` is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns `ilo` to `ihi`.

This is a modified version of `p?lahqr` from ScaLAPACK version 1.7.3. The following modifications were made:

- Workspace query functionality was added.
- Aggressive early deflation is implemented.
- Aggressive deflation (looking for two consecutive small subdiagonal elements by PSLACONSB) is abandoned.
- The returned Schur form is now in canonical form, i.e., the returned 2-by-2 blocks really correspond to complex conjugate pairs of eigenvalues.
- For some reason, the original version of `p?lahqr` sometimes did not read out the converged eigenvalues correctly. This is now fixed.

If  $lwork=-1$ , then a workspace query is assumed.

$iwork$  (global and local ) array of size  $ilwork$

This holds the some of the IBLK integer arrays.

$ilwork$  (local )

The size of the  $iwork$  array ( $ilwork \geq 3$  ).

## OUTPUT Parameters

$a$  If  $wantt$  is non-zero, the matrix  $A$  is upper quasi-triangular in rows and columns  $ilo:ih_i$ , with any 2-by-2 or larger diagonal blocks not yet in standard form. If  $wantt$  equals zero, the contents of  $a$  are unspecified on exit.

$wr, wi$  (global replicated ) array of size  $n$

The real and imaginary parts, respectively, of the computed eigenvalues  $ilo$  to  $ih_i$  are stored in the corresponding elements of  $wr$  and  $wi$ . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of  $wr$  and  $wi$ , say the  $i$ -th and  $(i+1)$ -th, with  $wi[i-1] > 0$  and  $wi[i] < 0$ . If  $wantt$  is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in  $a$ .  $a$  may be returned with larger diagonal blocks until the next release.

$z$  On exit  $z$  is updated; transformations are applied only to the submatrix  $Z(iloz:ihiz,ilo:ih_i)$ .

If  $wantz$  equals zero,  $z$  is not referenced.

$work[0]$  On exit, if  $info = 0$ ,  $work[0]$  returns the optimal  $lwork$ .

$info$  (global )

< 0: parameter number  $-info$  incorrect or inconsistent

= 0: successful exit

> 0: p?laqr1 failed to compute all the eigenvalues  $ilo$  to  $ih_i$  in a total of  $30*(ih_i-ilo+1)$  iterations; if  $info = i$ , elements  $i:ih_i-1$  of  $wr$  and  $wi$  contain those eigenvalues which have been successfully computed.

## Application Notes

This algorithm is very similar to [p?ahqr](#). Unlike [p?lahqr](#), instead of sending one double shift through the largest unreduced submatrix, this algorithm sends multiple double shifts and spaces them apart so that there can be parallelism across several processor row/columns. Another critical difference is that this algorithm aggregates multiple transforms together in order to apply them in a block fashion.

Current Notes and/or Restrictions:

- This code requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size. Unwise choices of too small a block size can lead to bad performance.
- This code requires  $a$  and  $z$  to be distributed identically and have identical contexts.
- This release currently does not have a function for resolving the Schur blocks into regular 2x2 form after this code is completed. Because of this, a significant performance impact is required while the deflation is done by sometimes a single column of processors.

- This code does not currently block the initial transforms so that none of the rows or columns for any bulge are completed until all are started. To offset pipeline start-up it is recommended that at least  $2 \times \text{LCM}(\text{NPROW}, \text{NPCOL})$  bulges are used (if possible)
- The maximum number of bulges currently supported is fixed at 32. In future versions this will be limited only by the incoming *work* array.
- The matrix *A* must be in upper Hessenberg form. If elements below the subdiagonal are nonzero, the resulting transforms may be nonsimilar. This is also true with the LAPACK function.
- For this release, it is assumed *rsrc\_*=*csrc\_*=0
- Currently, all the eigenvalues are distributed to all the nodes. Future releases will probably distribute the eigenvalues by the column partitioning.
- The internals of this function are subject to change.

## Description

`p?laqr2` accepts as input an upper Hessenberg matrix *A* and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output *A* is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of *A*. It is to be hoped that the final version of *A* has many zero subdiagonal entries.

This function handles small deflation windows which is affordable by one processor. Normally, it is called by `p?laqr1`. All the inputs are assumed to be valid without checking.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

*wantt* (global )

If  $wantz$  is non-zero, then the Hessenberg matrix  $A$  is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling function).

If  $wantz$  equals zero, then only enough of  $A$  is updated to preserve the eigenvalues.

$wantz$

(global )

If  $wantz$  is non-zero, then the orthogonal matrix  $Z$  is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling function).

If  $wantz$  equals zero, then  $z$  is not referenced.

$n$

(global )

The order of the matrix  $A$  and (if  $wantz$  is non-zero) the order of the orthogonal matrix  $Z$ .

$ktop, kbot$

(global )

It is assumed without a check that either  $kbot = n$  or  $A(kbot+1, kbot)=0$ .  $kbot$  and  $ktop$  together determine an isolated block along the diagonal of the Hessenberg matrix. However,  $A(ktop, ktop-1)=0$  is not essentially necessary if  $wantt$  is non-zero .

$nw$

(global )

Deflation window size.  $1 \leq nw \leq (kbot - ktop + 1)$ . Normally  $nw \geq 3$  if p?laqr2 is called by p?laqr1.

$a$

(local ) array of size  $lId\_a * LOC_c(n)$

The initial  $n$ -by- $n$  section of  $a$  stores the Hessenberg matrix undergoing aggressive early deflation.

$desc_a$

(global and local) array of size  $dlen\_$ .

The array descriptor for the distributed matrix  $A$ .

$ilo_z, ih_z$

(global )

Specify the rows of the matrix  $Z$  to which transformations must be applied if  $wantz$  is non-zero.  $1 \leq ilo_z \leq ih_z \leq n$ .

$z$

Array of size  $lId_z * LOC_c(n)$

If  $wantz$  is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix  $Z(ilo_z:ih_z, kbot:ktop)$ , stored in  $z$ , from the right.

If  $wantz$  is zero, then  $z$  is unreferenced.

$desc_z$

(global and local) array of size  $dlen\_$ .

The array descriptor for the distributed matrix  $Z$ .

$t$

(local workspace) array of size  $lDt * nw$ .

$lDt$

(local )

|            |                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------|
|            | The leading dimension of the array $t$ . $l_{dt} \geq nw$ .                                              |
| $v$        | (local workspace) array of size $l_{dv} * nw$ .                                                          |
| $l_{dv}$   | (local )                                                                                                 |
|            | The leading dimension of the array $v$ . $l_{dv} \geq nw$ .                                              |
| $wr, wi$   | (local workspace) array of size $k_{bot}$ .                                                              |
| $work$     | (local workspace) array of size $l_{work}$ .                                                             |
| $l_{work}$ | (local )                                                                                                 |
|            | $work(l_{work})$ is a local array and $l_{work}$ is assumed big enough so that $l_{work} \geq nw * nw$ . |

## OUTPUT Parameters

|          |                                                                                                                                                                                                                                                |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $a$      | On output $a$ has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.                                                          |
| $z$      |                                                                                                                                                                                                                                                |
| $ns$     | (global )                                                                                                                                                                                                                                      |
|          | The number of unconverged (that is, approximate) eigenvalues returned in $sr$ and $si$ that may be used as shifts by the calling function.                                                                                                     |
| $nd$     | (global )                                                                                                                                                                                                                                      |
|          | The number of converged eigenvalues uncovered by this function.                                                                                                                                                                                |
| $sr, si$ | (global ) array of size $k_{bot}$                                                                                                                                                                                                              |
|          | On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in $sr[k_{bot}-nd:ns]$ through $sr[k_{bot}-nd-1]$ and $si[k_{bot}-nd:ns]$ through $si[k_{bot}-nd-1]$ , respectively.                 |
|          | On processor #0, the real and imaginary parts of converged eigenvalues are stored in $sr[k_{bot}-nd]$ through $sr[k_{bot}-1]$ and $si[k_{bot}-nd]$ through $si[k_{bot}-1]$ , respectively. On other processors, these entries are set to zero. |

If  $lwork=-1$ , then a workspace query is assumed.

## OUTPUT Parameters

|            |                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $h$        | On output $h$ has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.                                                                                                                                                                                                                  |
| $z$        | IF $wantz$ is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix $Z(iloz:ihiz,kbot:ktop)$ from the right.<br>If $wantz$ is zero, then $z$ is unreferenced.                                                                                                                                                                        |
| $ns$       | (global )<br>The number of unconverged (that is, approximate) eigenvalues returned in $sr$ and $si$ that may be used as shifts by the calling function.                                                                                                                                                                                                                                                |
| $nd$       | (global )<br>The number of converged eigenvalues uncovered by this function.                                                                                                                                                                                                                                                                                                                           |
| $sr, si$   | (global ) array of size $kbot$ . The real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in $sr[kbot-nd-ns]$ through $sr[kbot-nd-1]$ and $si[kbot-nd-ns]$ through $si[kbot-nd-1]$ , respectively. The real and imaginary parts of converged eigenvalues are stored in $sr[kbot-nd]$ through $sr[kbot-1]$ and $si[kbot-nd]$ through $si[kbot-1]$ , respectively. |
| $work[0]$  | On exit, if $info = 0$ , $work[0]$ returns the optimal $lwork$                                                                                                                                                                                                                                                                                                                                         |
| $iwork[0]$ | On exit, if $info = 0$ , $iwork[0]$ returns the optimal $liwork$                                                                                                                                                                                                                                                                                                                                       |

## Description

This auxiliary function called by `p?laqr0` performs a single small-bulge multi-shift QR sweep by chasing separated groups of bulges along the main block diagonal of a Hessenberg matrix  $H$ .

## Input Parameters

|                         |                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>wantt</code>      | (global) scalar                                                                                                                                                                                                                                                                         |
|                         | <code>wantt</code> is non-zero if the quasi-triangular Schur factor is being computed. <code>wantt</code> is set to zero otherwise.                                                                                                                                                     |
| <code>wantz</code>      | (global) scalar                                                                                                                                                                                                                                                                         |
|                         | <code>wantz</code> is non-zero if the orthogonal Schur factor is being computed. <code>wantz</code> is set to zero otherwise.                                                                                                                                                           |
| <code>kacc22</code>     | (global)                                                                                                                                                                                                                                                                                |
|                         | Value 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates.                                                                                                                                                                                               |
|                         | = 0: <code>p?laqr5</code> does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries.                                                                                                                                           |
|                         | = 1: <code>p?laqr5</code> accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.                                                                                                                                                       |
|                         | = 2: <code>p?laqr5</code> accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.                                                                                  |
| <code>n</code>          | (global) scalar                                                                                                                                                                                                                                                                         |
|                         | The order of the Hessenberg matrix $H$ and, if <code>wantz</code> is non-zero, the order of the orthogonal matrix $Z$ .                                                                                                                                                                 |
| <code>ktop, kbot</code> | (global) scalar                                                                                                                                                                                                                                                                         |
|                         | These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either <code>ktop</code> = 1 or $H(ktop, ktop-1) = 0$ and either <code>kbot</code> = <code>n</code> or $H(kbot+1, kbot) = 0$ . |
| <code>nshfts</code>     | (global) scalar                                                                                                                                                                                                                                                                         |
|                         | <code>nshfts</code> gives the number of simultaneous shifts. <code>nshfts</code> must be positive and even.                                                                                                                                                                             |
| <code>sr, si</code>     | (global) Array of size <code>nshfts</code>                                                                                                                                                                                                                                              |
|                         | <code>sr</code> contains the real parts and <code>si</code> contains the imaginary parts of the <code>nshfts</code> shifts of origin that define the multi-shift QR sweep.                                                                                                              |
| <code>h</code>          | (local) Array of size $\text{ld}_h * \text{LOC}_c(n)$                                                                                                                                                                                                                                   |
|                         | On input <code>h</code> contains a Hessenberg matrix $H$ .                                                                                                                                                                                                                              |

## Description

The `p?laqsy` function equilibrates a symmetric distributed matrix  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$  using the scaling factors in the vectors `sr` and `sc`. The scaling factors are computed by `p?poequ`.

## Input Parameters

The scale factors for the matrix $A(ia:ia+m-1, ja:ja+n-1)$ . <code>sc</code> is aligned with the distributed matrix $A$ , and replicated across every process column. <code>sc</code> is tied to the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>scond</code>                | (global).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Ratio of the smallest  $sr[i]$  (respectively  $sc[j]$ ) to the largest  $sr[i]$  (respectively  $sc[j]$ ), with  $ia - 1 \leq i < ia + n - 1$  and  $ja - 1 \leq j < ja + n - 1$ .

$amax$  (global).

Absolute value of largest distributed submatrix entry.

## Output Parameters

$a$  On exit,

if  $equed = 'Y'$ , the equilibrated matrix:

$\text{diag}(sr_{ia}, \dots, sr_{ia+n-1}) * \text{sub}(A) * \text{diag}(sc_{ja}, \dots, sc_{ja+n-1})$ .

$equed$  (global).

Specifies whether or not equilibration was done.

= 'N': No equilibration.

= 'Y': Equilibration was done, that is,  $\text{sub}(A)$  has been replaced by:

$\text{diag}(sr_{ia}, \dots, sr_{ia+n-1}) * \text{sub}(A) * \text{diag}(sc_{ja}, \dots, sc_{ja+n-1})$ .

## p?lared1d

*Redistributes an array assuming that the input array,  $bycol$ , is distributed across rows and that all process columns contain the same copy of  $bycol$ .*

## Syntax

```
void pslared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , float *bycol ,
float *byall , float *work , MKL_INT *lwork);
void pdlared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , double
*bycol , double *byall , double *work , MKL_INT *lwork);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lared1d` function redistributes a 1D array. It assumes that the input array  $bycol$  is distributed across rows and that all process column contain the same copy of  $bycol$ . The output array  $byall$  is identical on all processes and contains the entire array.

## Input Parameters

$np$  = Number of local rows in  $bycol()$

$n$  (global)

The number of elements to be redistributed.  $n \geq 0$ .

$ia, ja$  (global)  $ia, ja$  must be equal to 1.

$desc$  (local) array of size 9. A 2D array descriptor, which describes  $bycol$ .

```

## Include Files

- mkl\_scalapack.h

## Description

The p?larf function applies a real/complex elementary reflector  $Q$  (or  $Q^T$ ) to a real/complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ , from either the left or the right.  $Q$  is represented in the form

$$Q = I - tau * v * v'$$

where  $tau$  is a real/complex scalar and  $v$  is a real/complex vector.

If  $tau = 0$ , then  $Q$  is taken to be the unit matrix.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Array of size  $lwork$ .

```

If $incv = 1$,
 if $side = 'L'$,
 if $ivcol = iccol$,
 $lwork \geq nqc0$
 else
 $lwork \geq mpc0 + \max(1, nqc0)$
 end if
 else if $side = 'R'$,
 $lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n +
 icooffc, nb_v, 0, 0, npcol), nb_v, 0, 0, lcmq))$
 end if
else if $incv = m_v$,
 if $side = 'L'$,
 $lwork \geq mpc0 + \max(\max(1, nqc0), \text{numroc}(
 \text{numroc}(m + iroffc, mb_v, 0, 0, nprow), mb_v, 0, 0, lcm))$
 else if $side = 'R'$,
 if $ivrow = icrow$,
 $lwork \geq mpc0$
 else
 $lwork \geq nqc0 + \max(1, mpc0)$
 end if
 end if
end if,

```

where  $lcm$  is the least common multiple of  $nprow$  and  $npcol$  and  $lcm = ilcm(nprow, npcol)$ ,  $lcmp = lcm / nprow$ ,  $lcmq = lcm / npcol$ ,

```

 $iroffc = \text{mod}(ic - 1, mb_c)$, $icooffc = \text{mod}(jc - 1, nb_c)$,
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$,
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol)$,
 $mpc0 = \text{numroc}(m + iroffc, mb_c, myrow, icrow, nprow)$,
 $nqc0 = \text{numroc}(n + icooffc, nb_c, mycol, iccol, npcol)$,
 $ilcm, \text{indxg2p}$, and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the function blacs_gridinfo .

```

## Output Parameters

*c*

(local).

On exit,  $\text{sub}(C)$  is overwritten by the  $Q^* \text{sub}(C)$  if  $side = 'L'$ ,

or  $\text{sub}(C) * Q$  if  $\text{side} = \text{'R'}$ .

## Description

The p?larfb function applies a real/complex block reflector  $Q$  or its transpose  $Q^T$ /conjugate transpose  $Q^H$  to a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  from the left or the right.

## Input Parameters

|               |                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------|
| <i>side</i>   | (global)                                                                                                         |
|               | if $\text{side} = \text{'L'}$ : apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the Left;  |
|               | if $\text{side} = \text{'R'}$ : apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the Right. |

ilcm, indxg2p, and numroc are ScalAPACK tool functions; myrow, mycol,
nrow, and ncol can be determined by calling the function
blacs_gridinfo.

```

## Output Parameters

*t*

(local).

Array of size *mb\_v* \* *mb\_v* if *storev* = 'R', and *nb\_v* \* *nb\_v* if *storev* = 'C'. The triangular matrix *t* is the representation of the block reflector.

*c*

(local).

On exit, *sub(C)* is overwritten by the *Q*\**sub(C)*, or *Q'*\**sub(C)*, or *sub(C)*\**Q*, or *sub(C)*\**Q'*. *Q'* is transpose (conjugate transpose) of *Q*.

### p?larfc

Applies the conjugate transpose of an elementary reflector to a general matrix.

## Syntax

```
void pclarfc (char *side , MKL_INT *m , MKL_INT *n , MKL_Complex8 *v , MKL_INT *iv ,
MKL_INT *jv , MKL_INT *descv , MKL_INT *incv , MKL_Complex8 *tau , MKL_Complex8 *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work);
void pzlarfc (char *side , MKL_INT *m , MKL_INT *n , MKL_Complex16 *v , MKL_INT *iv ,
MKL_INT *jv , MKL_INT *descv , MKL_INT *incv , MKL_Complex16 *tau , MKL_Complex16 *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work);
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?larfc` function applies a complex elementary reflector  $Q^H$  to a complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ , from either the left or the right.  $Q$  is represented in the form

$$Q = i - \tau u^* v^* v,$$

where  $\tau u$  is a complex scalar and  $v$  is a complex vector.

If  $\tau u = 0$ , then  $Q$  is taken to be the unit matrix.

## Input Parameters

nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npcol),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprov, and npcol can be determined by calling the function
blacs_gridinfo.

```

## Output Parameters

*c*

(local).

On exit, *sub(C)* is overwritten by the  $Q^H * \text{sub}(C)$  if *side* = 'L', or *sub(C)* \*  $Q^H$  if *side* = 'R'.

## Description

The `p?larfg` function generates a real/complex elementary reflector  $H$  of order  $n$ , such that

$$H^* \text{sub}(X) = H^* \begin{pmatrix} x(iax, jax) \\ x \end{pmatrix} = \begin{pmatrix} alpha \\ 0 \end{pmatrix}, \quad H^* H = I,$$

where  $\alpha$  is a scalar (a real scalar - for complex flavors), and  $\text{sub}(X)$  is an  $(n-1)$ -element real/complex distributed vector  $X(ix:ix+n-2, jx)$  if  $\text{incx} = 1$  and  $X(ix, jx:jx+n-2)$  if  $\text{incx} = m_x$ .  $H$  is represented in the form

$$H = I - tau * \begin{pmatrix} 1 \\ v \end{pmatrix} * (1 \ v')$$

where  $\tau$  is a real/complex scalar and  $v$  is a real/complex  $(n-1)$ -element vector. Note that  $H$  is not Hermitian.

If the elements of  $\text{sub}(X)$  are all zero (and  $X(iax, jax)$  is real for complex flavors), then  $\tau = 0$  and  $H$  is taken to be the unit matrix.

Otherwise  $1 \leq \text{real}(\tau) \leq 2$  and  $\text{abs}(\tau-1) \leq 1$ .

| <code>descx</code>    | (global and local)                                                                                                                                                                                                                     |
|                       | Array of size $dlen_$ . The array descriptor for the distributed matrix $X$ .                                                                                                                                                          |

*incx* (global)  
 The global increment for the elements of *x*. Only two values of *incx* are supported in this version, namely 1 and *m\_x*. *incx* must not be zero.

## Output Parameters

*alpha* (local)  
 On exit, *alpha* is computed in the process scope having the vector  $\text{sub}(X)$ .

*x* (local).  
 On exit, it is overwritten with the vector *v*.

*tau* (local).  
 Array of size  $\text{LOCc}(jx)$  if *incx* = 1, and  $\text{LOCr}(ix)$  otherwise. This array contains the Householder scalars related to the Householder vectors.  
*tau* is tied to the distributed matrix *X*.

### Description

The p?larft function forms the triangular factor *T* of a real/complex block reflector *H* of order *n*, which is defined as a product of *k* elementary reflectors.

If *direct* = 'F',  $H = H(1) * H(2) \dots * H(k)$ , and *T* is upper triangular;

If *direct* = 'B',  $H = H(k) * \dots * H(2) * H(1)$ , and *T* is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector  $H(i)$  is stored in the *i*-th column of the distributed matrix *V*, and

$$H = I - V * T * V'$$

If  $storev = 'R'$ , the vector which defines the elementary reflector  $H(i)$  is stored in the  $i$ -th row of the distributed matrix  $V$ , and

$$H = I - V'^* T^* V.$$

## Input Parameters

## Output Parameters

v

t (local)

Array of size  $nb_v * nb_v$  if  $storev = 'C'$ , and  $mb_v * mb_v$  otherwise. It contains the  $k$ -by- $k$  triangular factor of the block reflector associated with v.  
 If  $direct = 'F'$ , t is upper triangular;  
 if  $direct = 'B'$ , t is lower triangular.

## Application Notes

The shape of the matrix V and the storage of the vectors that define the  $H(i)$  is best illustrated by the following example with  $n = 5$  and  $k = 3$ . The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

$direct = 'F'$  and  $storev = 'C'$  :                   $direct = 'F'$  and  $storev = 'R'$

$$V(iv : iv + n - 1, jv : jv + k - 1) = \begin{bmatrix} 1 & & & & \\ v1 & 1 & & & \\ v1 & v2 & 1 & & \\ v1 & v2 & v3 & & \\ v1 & v2 & v3 & & \end{bmatrix}$$

$$V(iv : iv + k - 1, jv : jv + n - 1) = \begin{bmatrix} 1 & v1 & v1 & v1 & \\ & 1 & v2 & v2 & \\ & & 1 & v3 & \\ & & & 1 & v3 \end{bmatrix}$$

$direct = 'B'$  and  $storev = 'C'$

$$V(iv : iv + n - 1, jv : jv + k - 1) = \begin{bmatrix} v1 & v2v & v3 \\ v1 & v2 & v3 \\ 1 & v2 & v3 \\ & 1 & v3 \\ & & 1 \end{bmatrix}$$

$direct = 'B'$  and  $storev = 'R'$

$$V(iv : iv + k - 1, jv : jv + n - 1) = \begin{bmatrix} v1 & v1 & 1 & & \\ v2 & v2 & v2 & 1 & \\ v3 & v3 & v3 & v3 & 1 \end{bmatrix}$$

## Description

The `p?larz` function applies a real/complex elementary reflector  $Q$  (or  $Q^T$ ) to a real/complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ , from either the left or the right.  $Q$  is represented in the form

$$Q = I - \tau v v^T,$$

where  $\tau$  is a real/complex scalar and  $v$  is a real/complex vector.

If  $\tau = 0$ , then  $Q$  is taken to be the unit matrix.

$Q$  is a product of  $k$  elementary reflectors as returned by `p?tzrzf`.

## Input Parameters

|                   |                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Description

The `p?larzb` function applies a real/complex block reflector  $Q$  or its transpose  $Q^T$  (conjugate transpose  $Q^H$  for complex flavors) to a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  from the left or the right.

$Q$  is a product of  $k$  elementary reflectors as returned by `p?tzrzf`.

Currently, only `storev = 'R'` and `direct = 'B'` are supported.

## Input Parameters

|                     |                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------|
| <code>side</code>   | (global)                                                                                     |
|                     | if <code>side = 'L'</code> : apply $Q$ or $Q^T$ ( $Q^H$ for complex flavors) from the Left;  |
|                     | if <code>side = 'R'</code> : apply $Q$ or $Q^T$ ( $Q^H$ for complex flavors) from the Right. |
| <code>trans</code>  | (global)                                                                                     |
|                     | if <code>trans = 'N'</code> : No transpose, apply $Q$ ;                                      |
|                     | If <code>trans='T'</code> : Transpose, apply $Q^T$ (real flavors);                           |
|                     | If <code>trans='C'</code> : Conjugate transpose, apply $Q^H$ (complex flavors).              |
| <code>direct</code> | (global)                                                                                     |

|                     | Indicates how the vectors that define the elementary reflectors are stored:                  |
|                     | if <code>storev = 'C'</code> : columnwise (not supported ).                                  |
|                     | if <code>storev = 'R'</code> : rowwise.                                                      |
| <code>m</code>      | (global)                                                                                     |
|                     | The number of rows in the distributed submatrix $\text{sub}(C)$ . ( $m \geq 0$ ).            |
| <code>n</code>      | (global)                                                                                     |
|                     | The number of columns in the distributed submatrix $\text{sub}(C)$ . ( $n \geq 0$ ).         |
| <code>k</code>      | (global)                                                                                     |

The order of the matrix  $T$ . (= the number of elementary reflectors whose product defines the block reflector).

*l*

(global)

The columns of the distributed submatrix  $\text{sub}(A)$  containing the meaningful part of the Householder reflectors.

If  $\text{side} = \text{'L'}$ ,  $m \geq l \geq 0$ ,

if  $\text{side} = \text{'R'}$ ,  $n \geq l \geq 0$ .

*v*

(local).

Pointer into the local memory to an array of size  $\text{lld}_v * \text{LOCc}(j_v + m - 1)$  if  $\text{side} = \text{'L'}$ ,  $\text{lld}_v * \text{LOCc}(j_v + m - 1)$  if  $\text{side} = \text{'R'}$ .

It contains the local pieces of the distributed vectors  $V$  representing the Householder transformation as returned by `p?tzrzf`.

$\text{lld}_v \geq \text{LOCr}(iv + k - 1)$ .

*iv, jv*

(global)

The row and column indices in the global matrix  $V$  indicating the first row and the first column of the submatrix  $\text{sub}(V)$ , respectively.

*descv*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $V$ .

*t*

(local)

Array of size  $mb_v * mb_v$ .

The lower triangular matrix  $T$  in the representation of the block reflector.

*c*

(local).

Pointer into the local memory to an array of size  $\text{lld}_c * \text{LOCc}(j_c + n - 1)$ .

On entry, the  $m$ -by- $n$  distributed matrix  $\text{sub}(C)$ .

*ic, jc*

(global)

The row and column indices in the global matrix  $C$  indicating the first row and the first column of the submatrix  $\text{sub}(C)$ , respectively.

*descC*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $C$ .

*work*

(local).

Array of size *lwork*.

```

If storev = 'C' ,
 if side = 'L' ,
 lwork ≥(nqc0 + mpc0)* k
 else if side = 'R' ,
 lwork ≥ (nqc0 + max(npv0 + numroc(numroc(n+icoffc, nb_v, 0, 0,
npcol),
nb_v, 0, 0, lcmq), mpc0))* k
 end if
else if storev = 'R' ,
 if side = 'L' ,
 lwork ≥ (mpc0 + max(mqv0 + numroc(numroc(m+iroffc, mb_v, 0, 0,
nprov),
mb_v, 0, 0, lcmq), nqc0))* k
 else if side = 'R' ,
 lwork≥ (mpc0 + nqc0) * k
 end if
end if.

```

Here  $lcmq = lcm/npcol$  with  $lcm = iclm(nprov, npcol)$ ,  
 $iroffv = \text{mod}(iv-1, mb_v)$ ,  $icoffv = \text{mod}( jv-1, nb_v)$ ,  
 $ivrow = \text{indxg2p}(iv, mb_v, myrow, rsrc_v, nprov)$ ,  
 $ivcol = \text{indxg2p}(jv, nb_v, mycol, csrc_v, npcol)$ ,  
 $mqv0 = \text{numroc}(m+icoffv, nb_v, mycol, ivcol, npcol)$ ,  
 $npv0 = \text{numroc}(n+iroffv, mb_v, myrow, ivrow, nprov)$ ,  
 $iroffc = \text{mod}(ic-1, mb_c)$ ,  $icoffc = \text{mod}( jc-1, nb_c)$ ,  
 $icrow= \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprov)$ ,  
 $iccol= \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol)$ ,  
 $mpc0 = \text{numroc}(m+iroffc, mb_c, myrow, icrow, nprov)$ ,  
 $npc0 = \text{numroc}(n+icoffc, mb_c, myrow, icrow, nprov)$ ,  
 $nqc0 = \text{numroc}(n+icoffc, nb_c, mycol, iccol, npcol)$ ,  
 $ilcm$ ,  $\text{indxg2p}$ , and  $\text{numroc}$  are ScalAPACK tool functions;  $myrow$ ,  $mycol$ ,  
 $nprov$ , and  $npcol$  can be determined by calling the function  
 $\text{blacs\_gridinfo}$ .

## Output Parameters

*c*

(local).

On exit,  $\text{sub}(C)$  is overwritten by the  $Q^* \text{sub}(C)$ , or  $Q'^* \text{sub}(C)$ , or  $\text{sub}(C) * Q$ , or  $\text{sub}(C) * Q'$ , where  $Q'$  is the transpose (conjugate transpose) of  $Q$ .

### p?larzc

Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by [p?tzrzf](#) to a general matrix.

## Syntax

```
void pclarzc (char *side , MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex8 *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_INT *incv , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work);
void pzlarzc (char *side , MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex16 *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_INT *incv , MKL_Complex16 *tau ,
MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work);
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?larzc` function applies a complex elementary reflector  $Q^H$  to a complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ , from either the left or the right.  $Q$  is represented in the form

$$Q = i - \tau \cdot v \cdot v^H,$$

where  $\tau$  is a complex scalar and  $v$  is a complex vector.

If  $\tau = 0$ , then  $Q$  is taken to be the unit matrix.

$Q$  is a product of  $k$  elementary reflectors as returned by [p?tzrzf](#).

## Input Parameters

|                   |                                                                                                                     |

| <code>side</code> | (global)                                                                                                            |
|                   | if <code>side</code> = 'L': form $Q^H * \text{sub}(C)$ ;                                                            |
|                   | if <code>side</code> = 'R': form $\text{sub}(C) * Q^H$ .                                                            |
| <code>m</code>    | (global)                                                                                                            |
|                   | The number of rows in the distributed matrix $\text{sub}(C)$ . ( $m \geq 0$ ).                                      |
| <code>n</code>    | (global)                                                                                                            |
|                   | The number of columns in the distributed matrix $\text{sub}(C)$ . ( $n \geq 0$ ).                                   |
| <code>l</code>    | (global)                                                                                                            |
|                   | The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. |
|                   | If <code>side</code> = 'L', $m \geq l \geq 0$ ,                                                                     |

*if side = 'R',  $n \geq l \geq 0$ .*

*v* (local).

Pointer into the local memory to an array of size  $l/d_v * LOCc(n_v)$  containing the local pieces of the global distributed matrix  $V$  representing the Householder transformation  $Q$ ,

$V(iv:iv+l-1, jv)$  if *side* = 'L' and *incv* = 1,  
 $V(iv, jv:jv+l-1)$  if *side* = 'L' and *incv* =  $m_v$ ,  
 $V(iv:iv+l-1, jv)$  if *side* = 'R' and *incv* = 1,  
 $V(iv, jv:jv+l-1)$  if *side* = 'R' and *incv* =  $m_v$ .

The vector *v* in the representation of  $Q$ . *v* is not used if *tau* = 0.

*iv, jv* (global)

The row and column indices in the global matrix  $V$  indicating the first row and the first column of the matrix sub( $V$ ), respectively.

*descv* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix  $V$ .

*incv* (global)

The global increment for the elements of  $V$ . Only two values of *incv* are supported in this version, namely 1 and  $m_v$ .

*incv* must not be zero.

*tau* (local)

Array of size  $LOCc(jv)$  if *incv* = 1, and  $LOCr(iv)$  otherwise. This array contains the Householder scalars related to the Householder vectors.

*tau* is tied to the distributed matrix  $V$ .

*c* (local).

Pointer into the local memory to an array of size  $l/d_c * LOCc(jc+n-1)$ , containing the local pieces of sub( $C$ ).

*ic, jc* (global)

The row and column indices in the global matrix  $C$  indicating the first row and the first column of the matrix sub( $C$ ), respectively.

*descC* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix  $C$ .

*work* (local).

```
If incv = 1,
 if side = 'L' ,
 if ivcol = iccol,

*t , MKL_Complex16 *work);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?larzt` function forms the triangular factor  $T$  of a real/complex block reflector  $H$  of order greater than  $n$ , which is defined as a product of  $k$  elementary reflectors as returned by `p?tzrzf`.

If  $\text{direct} = \text{'F'}$ ,  $H = H(1)*H(2)*\dots*H(k)$ , and  $T$  is upper triangular;

If  $\text{direct} = \text{'B'}$ ,  $H = H(k)*\dots*H(2)*H(1)$ , and  $T$  is lower triangular.

If  $\text{storev} = \text{'C'}$ , the vector which defines the elementary reflector  $H(i)$ , is stored in the  $i$ -th column of the array  $v$ , and

$H = i - v * t * v'$ .

If  $\text{storev} = \text{'R'}$ , the vector, which defines the elementary reflector  $H(i)$ , is stored in the  $i$ -th row of the array  $v$ , and

$H = i - v' * t * v$

Currently, only  $\text{storev} = \text{'R'}$  and  $\text{direct} = \text{'B'}$  are supported.

## Input Parameters

`direct`

(global)

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

if  $\text{direct} = \text{'F'}$ :  $H = H(1)*H(2)*\dots*H(k)$  (Forward, not supported)

if  $\text{direct} = \text{'B'}$ :  $H = H(k)*\dots*H(2)*H(1)$  (Backward).

`storev`

(global)

Specifies how the vectors which defines the elementary reflectors are stored:

if  $\text{storev} = \text{'C'}$ : columnwise (not supported);

if  $\text{storev} = \text{'R'}$ : rowwise.

`n`

(global)

The order of the block reflector  $H$ .  $n \geq 0$ .

`k`

(global)

The order of the triangular factor  $T$  (= the number of elementary reflectors).

$1 \leq k \leq mb_v (= nb_v)$ .

`v`

Pointer into the local memory to an array of local size  $LOCr(iv+k-1) * LOCc(jv+n-1)$ .

The distributed matrix  $V$  contains the Householder vectors. See *Application Notes* below.

## Application Notes

The shape of the matrix  $V$  and the storage of the vectors which define the  $H(i)$  is best illustrated by the following example with  $n = 5$  and  $k = 3$ . The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

*direct='F'* and *storev='C'*

$$\begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

$$v = \begin{array}{cccc} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot & \cdot \end{array}$$

*direct='F' and storev='R':*

$$\left[ \begin{array}{ccccccccc} & & & \overbrace{\text{v}}^{\text{x}} & & & & & \\ \text{v1} & \text{v1} & \text{v1} & \text{v1} & \text{v1} & \cdot & \cdot & \cdot & 1 \\ \text{v2} & \text{v2} & \text{v2} & \text{v2} & \text{v2} & \cdot & \cdot & \cdot & 1 \\ \text{v3} & \text{v3} & \text{v3} & \text{v3} & \text{v3} & \cdot & \cdot & \cdot & 1 \end{array} \right]$$

*direct='B' and storev='C':*

$$\begin{aligned} 1 \\ . & \quad 1 \\ . & \quad . & \quad 1 \\ . & \quad . & \quad . \\ \text{v} = & \quad . & \quad . & \quad . \\ & \left[ \begin{array}{ccc} \text{v1} & \text{v2} & \text{v3} \\ \text{v1} & \text{v2} & \text{v3} \end{array} \right] \end{aligned}$$

*direct='B' and storev='R':*

## Description

The p?blascl function multiplies the  $m$ -by- $n$  real/complex distributed matrix sub( $A$ ) denoting  $A(ia:ia+m-1, ja:ja+n-1)$  by the real/complex scalar  $cto/cfrom$ . This is done without over/underflow as long as the final result  $cto*A(i,j)/cfrom$  does not over/underflow. *type* specifies that sub( $A$ ) may be full, upper triangular, lower triangular or upper Hessenberg.

## Input Parameters

|                   |                                                                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i>       | (global)                                                                                                                                                                                                                     |
|                   | <i>type</i> indicates the storage type of the input distributed matrix.                                                                                                                                                      |
|                   | if <i>type</i> = 'G': sub( $A$ ) is a full matrix,                                                                                                                                                                           |
|                   | if <i>type</i> = 'L': sub( $A$ ) is a lower triangular matrix,                                                                                                                                                               |
|                   | if <i>type</i> = 'U': sub( $A$ ) is an upper triangular matrix,                                                                                                                                                              |
|                   | if <i>type</i> = 'H': sub( $A$ ) is an upper Hessenberg matrix.                                                                                                                                                              |

Array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

## Output Parameters

- a* (local).  
On exit, this array contains the local pieces of the distributed matrix multiplied by *cto/cfrom*.
- info* (local)
  - if *info* = 0: the execution is successful.
  - if *info* < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = -(*i*\*100+*j*),
  - if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

## p?lase2

*Initializes an m-by-n distributed matrix.*

---

## Syntax

```
void pslase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const float* alpha,
const float* beta, float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT*
desca);

void pdlase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const double*
alpha, const double* beta, double* a, const MKL_INT* ia, const MKL_INT* ja, const
MKL_INT* desca);

void pclase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const MKL_Complex8* *
alpha, const MKL_Complex8* beta, MKL_Complex8* a, const MKL_INT* ia, const MKL_INT* ja,
const MKL_INT* desca);

void pzlace2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const
MKL_Complex16* alpha, const MKL_Complex16* beta, MKL_Complex16* a, const MKL_INT* ia,
const MKL_INT* ja, const MKL_INT* desca);
```

## Include Files

- `mkl_scalapack.h`

## Description

`p?lase2` initializes an *m*-by-*n* distributed matrix `sub( A )` denoting  $A_{(ia:ia+m-1,ja:ja+n-1)}$  to *beta* on the diagonal and *alpha* on the off-diagonals. `p?lase2` requires that only the dimension of the matrix operand is distributed.

## Input Parameters

- uplo* (global)
  - Specifies the part of the distributed matrix `sub( A )` to be set:
  - = 'U': Upper triangular part is set; the strictly lower triangular part of `sub( A )` is not changed;

= 'L': Lower triangular part is set; the strictly upper triangular part of sub(  $A$  ) is not changed;

Otherwise: All of the matrix sub(  $A$  ) is set.

*m*

(global)

The number of rows to be operated on i.e the number of rows of the distributed submatrix sub(  $A$  ).  $m \geq 0$ .

*n*

(global)

The number of columns to be operated on i.e the number of columns of the distributed submatrix sub(  $A$  ).  $n \geq 0$ .

*alpha*

(global)

The constant to which the off-diagonal elements are to be set.

*beta*

(global)

The constant to which the diagonal elements are to be set.

*ia*

(global)

The row index in the global array *a* indicating the first row of sub(  $A$  ).

*ja*

(global)

The column index in the global array *a* indicating the first column of sub(  $A$  ).

*desca*

(global and local)

Array of size *dlen\_*.

The array descriptor for the distributed matrix  $A$ .

## Output Parameters

*a*

(local)

Pointer into the local memory to an array of size  $ld_a * LOCc(ja+n-1)$ .

This array contains the local pieces of the distributed matrix sub(  $A$  ) to be set.

On exit, the leading  $m$ -by- $n$  submatrix sub(  $A$  ) is set as follows:

if *uplo* = 'U',  $A(ia+i-1, ja+j-1) = alpha$ ,  $1 \leq i \leq j-1$ ,  $1 \leq j \leq n$ ,

if *uplo* = 'L',  $A(ia+i-1, ja+j-1) = alpha$ ,  $j+1 \leq i \leq m$ ,  $1 \leq j \leq n$ ,

otherwise,  $A(ia+i-1, ja+j-1) = alpha$ ,  $1 \leq i \leq m$ ,  $1 \leq j \leq n$ ,  $ia+i \neq ja+j$ ,

and, for all *uplo*,  $A(ia+i-1, ja+i-1) = beta$ ,  $1 \leq i \leq \min(m, n)$ .

## p?laset

Initializes the offdiagonal elements of a matrix to *alpha* and the diagonal elements to *beta*.

## Syntax

```
void pslaset (char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float *beta , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
void pdlaset (char *uplo , MKL_INT *m , MKL_INT *n , double *alpha , double *beta ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
void pclaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *alpha , MKL_Complex8
*beta , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
void pzlaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *alpha ,
MKL_Complex16 *beta , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?laset` function initializes an  $m$ -by- $n$  distributed matrix  $\text{sub}(A)$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  to  $\beta$  on the diagonal and  $\alpha$  on the offdiagonals.

## Input Parameters

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>uplo</code>  | (global)                                                                                                                 |
|                    | Specifies the part of the distributed matrix $\text{sub}(A)$ to be set:                                                  |
|                    | if <code>uplo</code> = 'U': upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not changed; |
|                    | if <code>uplo</code> = 'L': lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not changed. |
|                    | Otherwise: all of the matrix $\text{sub}(A)$ is set.                                                                     |
| <code>m</code>     | (global)                                                                                                                 |
|                    | The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).                                           |
| <code>n</code>     | (global)                                                                                                                 |
|                    | The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).                                        |
| <code>alpha</code> | (global).                                                                                                                |
|                    | The constant to which the offdiagonal elements are to be set.                                                            |
| <code>beta</code>  | (global).                                                                                                                |
|                    | The constant to which the diagonal elements are to be set.                                                               |

## Output Parameters

|                |                                                                                                                                                                       |

| <code>a</code> | (local).                                                                                                                                                              |
|                | Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$ .                                                                                            |
|                | This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading $m$ -by- $n$ matrix $\text{sub}(A)$ is set as follows: |
|                | if <code>uplo</code> = 'U', $A(ia+i-1, ja+j-1) = \alpha$ , $1 \leq i \leq j-1$ , $1 \leq j \leq n$ ,                                                                  |
|                | if <code>uplo</code> = 'L', $A(ia+i-1, ja+j-1) = \alpha$ , $j+1 \leq i \leq m$ , $1 \leq j \leq n$ ,                                                                  |

otherwise,  $A(ia+i-1, ja+j-1) = \alpha$ ,  $1 \leq i \leq m$ ,  $1 \leq j \leq n$ ,  $ia+i \neq ja+j$ , and, for all  $uplo$ ,  $A(ia+i-1, ja+i-1) = \beta$ ,  $1 \leq i \leq \min(m, n)$ .

*ia, ja*

(global)

The column and row indices in the distributed matrix  $A$  indicating the first row and column of the matrix  $\text{sub}(A)$ , respectively.

*desca*

(global and local)

Array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

## Description

The `p?lasmsub` function looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This function performs a global maximum and must be called by all processes.

## Input Parameters

*a*

(local)

Array of size  $ld_a * LOCc(n_a)$ .

On entry, the Hessenberg matrix whose tridiagonal part is being scanned.  
Unchanged on exit.

*desca*

(global and local)

Array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

*i*

(global)

The global location of the bottom of the unreduced submatrix of  $A$ .  
Unchanged on exit.

|               |                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>i</i>      | (global)                                                                                                                                                                                |
|               | The global location of the top of the unreduced submatrix of <i>A</i> . Unchanged on exit.                                                                                              |
| <i>smlnum</i> | (global)                                                                                                                                                                                |
|               | On entry, a "small number" for the given matrix. Unchanged on exit. The machine-dependent constants for the stopping criterion.                                                         |
| <i>lwork</i>  | (local)                                                                                                                                                                                 |
|               | This must be at least $2 * \text{ceil}(\text{ceil}((i-1)/mb\_a) / \text{lcm}(nprov, npcol))$ . Here <i>lcm</i> is least common multiple and <i>nprovxncol</i> is the logical grid size. |

## Output Parameters

|            |                                                                                                              |
|------------|--------------------------------------------------------------------------------------------------------------|
| <i>k</i>   | (global)                                                                                                     |
|            | On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $1 \leq k \leq i-1$ . |
| <i>buf</i> | (local).                                                                                                     |
|            | Array of size <i>lwork</i> .                                                                                 |

## Application Notes

This routine parallelizes the code from `?lahqr` that looks for a single small subdiagonal element.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lasrt

*Sorts the numbers in an array and the corresponding vectors in increasing order.*

---

## Syntax

```
void pslasrt (const char* id, const MKL_INT* n, float* d, const float* q, const
MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, float* work, const MKL_INT*
lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);

void pdlasrt (const char* id, const MKL_INT* n, double* d, const double* q, const
MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, double* work, const MKL_INT*
lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);
```

## Include Files

- `mkl_scalapack.h`

## Description

`p?lasrt` sorts the numbers in *d* and the corresponding vectors in *q* in increasing order.

## Input Parameters

|           |                                           |
|-----------|-------------------------------------------|
| <i>id</i> | (global)                                  |
|           | = 'I': sort <i>d</i> in increasing order; |

= 'D': sort  $d$  in decreasing order. (NOT IMPLEMENTED YET)

$n$

(global)

The number of columns to be operated on i.e the number of columns of the distributed submatrix sub(  $Q$  ).  $n \geq 0$ .

$d$

(global)

Array, size ( $n$ )

$q$

(local)

Pointer into the local memory to an array of size  $lld_q * LOCc(jq+n-1)$ .

This array contains the local pieces of the distributed matrix sub(  $A$  ) to be copied from.

$iq$

(global)

The row index in the global array  $A$  indicating the first row of sub(  $Q$  ).

$jq$

(global)

The column index in the global array  $A$  indicating the first column of sub(  $Q$  ).

$descq$

(global and local)

Array of size  $dlen_$ .

The array descriptor for the distributed matrix  $A$ .

$work$

(local)

Array, size ( $lwork$ )

$lwork$

(local)

The size of the array  $work$ .

$lwork = \text{MAX}( n, \text{NP} * (\text{NB} + \text{NQ}) )$ , where  $\text{NP} = \text{numroc}( n, \text{NB}, \text{MYROW}, \text{IAROW}, \text{NPROW} )$ ,  $\text{NQ} = \text{numroc}( n, \text{NB}, \text{MYCOL}, \text{DESCQ}( \text{csrc}_ ), \text{NPCOL} )$ .

$\text{numroc}$  is a ScaLAPACK tool function.

$iwork$

(local)

Array, size ( $liwork$ )

$liwork$

(local)

The size of the array  $iwork$ .

$liwork = n + 2*\text{NB} + 2*\text{NPCOL}$

## Output Parameters

$d$

On exit, the numbers in  $d$  are sorted in increasing order.

$info$

(global)

= 0: successful exit

$< 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry had an illegal value, then  $\text{info} = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $\text{info} = -i$ .

## p?lassq

Updates a sum of squares represented in scaled form.

### Syntax

```
void pslassq (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *scale , float *sumsq);
void pdlassq (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *scale , double *sumsq);
void pclassq (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *scale , float *sumsq);
void pzlassq (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *scale , double *sumsq);
```

### Include Files

- mkl\_scalapack.h

### Description

The `p?lassq` function returns the values  $scl$  and  $sumsq$  such that

$$scl^2 * sumsq = x_1^2 + \dots + x_n^2 + scale^2 * sumsq,$$

where

$$x_i = \text{sub}(X) = X(ix + (jx-1)*m_x + (i-1)*incx) \text{ for pslassq/pdlassq,}$$

$$x_i = \text{abs}(X(ix + (jx-1)*m_x + (i-1)*incx)) \text{ for pclassq/pzlassq.}$$

For real functions `pslassq/pdlassq` the value of  $sumsq$  is assumed to be non-negative and  $scl$  returns the value

$$scl = \max(scale, \text{abs}(x_i)).$$

For complex functions `pclassq/pzlassq` the value of  $sumsq$  is assumed to be at least unity and the value of  $ssq$  will then satisfy

$$1.0 \leq ssq \leq sumsq + 2n$$

Value  $scale$  is assumed to be non-negative and  $scl$  returns the value

$$scl = \max_i \left( scale, \text{abs}(\text{real}(x_i)), \text{abs}(\text{aimag}(x_i)) \right)$$

For all functions `p?lassq` values  $scale$  and  $sumsq$  must be supplied in `scale` and `sumsq` respectively, and `scale` and `sumsq` are overwritten by `scl` and `ssq` respectively.

All functions `p?lassq` make only one pass through the vector `sub(X)`.

### Input Parameters

`n`

(global)

The length of the distributed vector `sub(x)`.

|              |                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i>     | The array that stores the vector for which a scaled sum of squares is computed:                                                                                                      |
|              | $x[ix + (jx-1)*m_x + i*incx], \quad 0 \leq i < n.$                                                                                                                                   |
| <i>ix</i>    | (global)                                                                                                                                                                             |
|              | The row index in the global matrix $X$ indicating the first row of $\text{sub}(X)$ .                                                                                                 |
| <i>jx</i>    | (global)                                                                                                                                                                             |
|              | The column index in the global matrix $X$ indicating the first column of $\text{sub}(X)$ .                                                                                           |
| <i>descx</i> | (global and local) array of size <i>dlen_</i> .                                                                                                                                      |
|              | The array descriptor for the distributed matrix $X$ .                                                                                                                                |
| <i>incx</i>  | (global)                                                                                                                                                                             |
|              | The global increment for the elements of $X$ . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>m_x</i> . The argument <i>incx</i> must not equal zero. |
| <i>scale</i> | (local).                                                                                                                                                                             |
|              | On entry, the value <i>scale</i> in the equation above.                                                                                                                              |
| <i>sumsq</i> | (local)                                                                                                                                                                              |
|              | On entry, the value <i>sumsq</i> in the equation above.                                                                                                                              |

## Output Parameters

|              |                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>scale</i> | (local).                                                                                                                                |
|              | On exit, <i>scale</i> is overwritten with <i>scl</i> , the scaling factor for the sum of squares.                                       |
| <i>sumsq</i> | (local).                                                                                                                                |
|              | On exit, <i>sumsq</i> is overwritten with the value <i>smsq</i> , the basic sum of squares from which <i>scl</i> has been factored out. |

## Description

The `p?laswp` function performs a series of row or column interchanges on the distributed matrix `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`. One interchange is initiated for each of rows or columns  $k_1$  through  $k_2$  of `sub(A)`. This function assumes that the pivoting information has already been broadcast along the process row or column. Also note that this function will only work for  $k_1-k_2$  being in the same  $mb$  (or  $nb$ ) block. If you want to pivot a full matrix, use `p?lapiv`.

## Input Parameters

|                     |                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>direc</code>  | (global)                                                                                                                                                                                                |
|                     | Specifies in which order the permutation is applied:                                                                                                                                                    |
|                     | = ' <code>F</code> ' - forward,                                                                                                                                                                         |
|                     | = ' <code>B</code> ' - backward.                                                                                                                                                                        |
| <code>rowcol</code> | (global)                                                                                                                                                                                                |
|                     | Specifies if the rows or columns are permuted:                                                                                                                                                          |
|                     | = ' <code>R</code> ' - rows,                                                                                                                                                                            |
|                     | = ' <code>C</code> ' - columns.                                                                                                                                                                         |
| <code>n</code>      | (global)                                                                                                                                                                                                |
|                     | If <code>rowcol='R'</code> , the length of the rows of the distributed matrix <code>A(*, ja:ja+n-1)</code> to be permuted;                                                                              |
|                     | If <code>rowcol='C'</code> , the length of the columns of the distributed matrix <code>A(ia:ia+n-1, *)</code> to be permuted;                                                                           |
| <code>a</code>      | (local)                                                                                                                                                                                                 |
|                     | Pointer into the local memory to an array of size $lld_a * LOCc(n_a)$ . On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied. |
| <code>ia</code>     | (global)                                                                                                                                                                                                |
|                     | The row index in the global matrix <code>A</code> indicating the first row of <code>sub(A)</code> .                                                                                                     |
| <code>ja</code>     | (global)                                                                                                                                                                                                |
|                     | The column index in the global matrix <code>A</code> indicating the first column of <code>sub(A)</code> .                                                                                               |
| <code>desca</code>  | (global and local) array of size <code>dlen_</code> .                                                                                                                                                   |
|                     | The array descriptor for the distributed matrix <code>A</code> .                                                                                                                                        |
| <code>k1</code>     | (global)                                                                                                                                                                                                |
|                     | The first element of <code>ipiv</code> for which a row or column interchange will be done.                                                                                                              |
| <code>k2</code>     | (global)                                                                                                                                                                                                |
|                     | The last element of <code>ipiv</code> for which a row or column interchange will be done.                                                                                                               |

*ipiv* (local)  
 Array of size  $LOCr(m\_a) + mb\_a$  for row pivoting and  $LOCr(n\_a) + nb\_a$  for column pivoting. This array is tied to the matrix  $A$ ,  $ipiv[k]=l$  implies rows (or columns)  $k+1$  and  $l$  are to be interchanged,  $k = 0, 1, \dots, \text{size}(ipiv) - 1$ .

## Output Parameters

*A* (local)  
 On exit, the permuted distributed matrix.

## Description

This function computes the trace of an  $n$ -by- $n$  distributed matrix  $\text{sub}(A)$  denoting  $A(ia:ia+n-1, ja:ja+n-1)$ . The result is left on every process of the grid.

## Input Parameters

*n* (global)  
 The number of rows and columns to be operated on, that is, the order of the distributed matrix  $\text{sub}(A)$ .  $n \geq 0$ .

*a* (local).  
 Pointer into the local memory to an array of size  $lId\_a * LOCc(ja+n-1)$  containing the local pieces of the distributed matrix, the trace of which is to be computed.

*ia, ja* (global) The row and column indices respectively in the global matrix  $A$  indicating the first row and the first column of the matrix  $\text{sub}(A)$ , respectively.

*desca* (global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

## Output Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <code>val</code> | The value returned by the function. |
|------------------|-------------------------------------|

## Description

The `p?latrd` function reduces *nb* rows and columns of a real symmetric or complex Hermitian matrix  $\text{sub}(A) = A(i_a:i_a+n-1, j_a:j_a+n-1)$  to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation  $Q^* \text{sub}(A) Q$ , and returns the matrices  $V$  and  $W$ , which are needed to apply the transformation to the unreduced part of  $\text{sub}(A)$ .

If `uplo` = `U`, `p?latrd` reduces the last *nb* rows and columns of a matrix, of which the upper triangle is supplied;

if `uplo` = `L`, `p?latrd` reduces the first *nb* rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary function called by `p?syrtd/p?hetrd`.

## Input Parameters

|                      |                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>uplo</code>    | (global)                                                                                                          |
|                      | Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored: |
| = <code>'U'</code> : | Upper triangular                                                                                                  |
| = <code>'L'</code> : | Lower triangular.                                                                                                 |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

if  $uplo = 'L'$ , the first  $nb$  columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of  $\text{sub}(A)$ ; the elements below the diagonal with the array  $\tau$  represent the orthogonal/unitary matrix  $Q$  as a product of elementary reflectors.

 $d$ 

(local)

Array of size  $\text{LOCc}(ja+n-1)$ .

The diagonal elements of the tridiagonal matrix  $T$ :  $d[i] = A(i+1,i+1)$ ,  $i = 0, 1, \dots, \text{LOCc}(ja+n-1)-1$ .  $d$  is tied to the distributed matrix  $A$ .

 $e$ 

(local)

Array of size  $\text{LOCc}(ja+n-1)$  if  $uplo = 'U'$ ,  $\text{LOCc}(ja+n-2)$  otherwise.

The off-diagonal elements of the tridiagonal matrix  $T$ :

$$\begin{aligned} e[i] &= A(i+1, i+2) \text{ if } uplo = 'U', \\ e[i] &= A(i+2, i+1) \text{ if } uplo = 'L', \\ i &= 0, 1, \dots, \text{LOCc}(ja+n-1)-1. \end{aligned}$$

$e$  is tied to the distributed matrix  $A$ .

 $\tau$ 

(local)

Array of size  $\text{LOCc}(ja+n-1)$ . This array contains the scalar factors of the elementary reflectors.  $\tau$  is tied to the distributed matrix  $A$ .

 $w$ 

(local)

Pointer into the local memory to an array of size  $lwd_w * nb_w$ . This array contains the local pieces of the  $n$ -by- $nb_w$  matrix  $w$  required to update the unreduced part of  $\text{sub}(A)$ .

## Application Notes

If  $uplo = 'U'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v^T,$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(i:n) = 0$  and  $v(i-1) = 1$ ;  $v(1:i-1)$  is stored on exit in  $A(ia:ia+i-1, ja+i)$ , and  $\tau$  in  $\tau[ja+i-2]$ .

If  $uplo = L$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v^T,$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i) = 0$  and  $v(i+1) = 1$ ;  $v(i+2:n)$  is stored on exit in  $A(ia+i+1: ia+n-1, ja+i-1)$ , and  $\tau$  in  $\tau[ja+i-2]$ .

The elements of the vectors  $v$  together form the  $n$ -by- $nb$  matrix  $V$  which is needed, with  $W$ , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank- $2k$  update of the form:

$$\text{sub}(A) := \text{sub}(A) - v w^T - w v^T.$$

The contents of  $a$  on exit are illustrated by the following examples with

$n = 5$  and  $nb = 2$ :

|                                                                                                                             |                                                                                                                             |
|-----------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>if <math>uplo='U'</math>:</b>                                                                                            | <b>if <math>uplo='L'</math>:</b>                                                                                            |
| $\begin{bmatrix} a & a & a & v_4 & v_5 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & & d & 1 \\ & & & & d \end{bmatrix}$ | $\begin{bmatrix} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{bmatrix}$ |

where  $d$  denotes a diagonal element of the reduced matrix,  $a$  denotes an element of the original matrix that is unchanged, and  $v_i$  denotes an element of the vector defining  $H(i)$ .

## Description

The p?latrs function solves a triangular system of equations  $Ax = sb$ ,  $A^T x = sb$  or  $A^H x = sb$ , where  $s$  is a scale factor set to prevent overflow. The description of the function will be extended in the future releases.

## Input Parameters

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>           | Specifies whether the matrix $A$ is upper or lower triangular.<br>= 'U': Upper triangular<br>= 'L': Lower triangular                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>trans</i>          | Specifies the operation applied to $Ax$ .<br>= 'N': Solve $Ax = s*b$ (no transpose)<br>= 'T': Solve $A^Tx = s*b$ (transpose)<br>= 'C': Solve $A^Hx = s*b$ (conjugate transpose),<br>where $s$ - is a scale factor                                                                                                                                                                                                                                                                                                                                                                            |
| <i>diag</i>           | Specifies whether or not the matrix $A$ is unit triangular.<br>= 'N': Non-unit triangular<br>= 'U': Unit triangular                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>normin</i>         | Specifies whether <i>cnorm</i> has been set or not.<br>= 'Y': <i>cnorm</i> contains the column norms on entry;<br>= 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> .                                                                                                                                                                                                                                                                                                                                                                  |
| <i>n</i>              | The order of the matrix $A$ . $n \geq 0$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>a</i>              | Array of size $lda * n$ . Contains the triangular matrix $A$ .<br>If <i>uplo</i> = U, the leading $n$ -by- $n$ upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced.<br>If <i>uplo</i> = 'L', the leading $n$ -by- $n$ lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced.<br>If <i>diag</i> = 'U', the diagonal elements of <i>a</i> are also not referenced and are assumed to be 1. |
| <i>ia</i> , <i>ja</i> | (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>desca</i>          | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>x</i>              | Array of size $n$ . On entry, the right hand side $b$ of the triangular system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>ix</i>             | (global).The row index in the global matrix $X$ indicating the first row of $\text{sub}(x)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>jx</i>             | (global)<br>The column index in the global matrix $X$ indicating the first column of $\text{sub}(X)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>descx</i> | (global and local)                                                                                                                                                                                                                                                                                                                                                                                                                     |
|              | Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .                                                                                                                                                                                                                                                                                                                                                |
| <i>cnorm</i> | Array of size <i>n</i> . If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm[j]</i> contains the norm of the off-diagonal part of the ( <i>j</i> +1)-th column of the matrix <i>A</i> , <i>j</i> =0, 1, ..., <i>n</i> -1. If <i>trans</i> = 'N', <i>cnorm[j]</i> must be greater than or equal to the infinity-norm, and if <i>trans</i> = 'T' or 'C', <i>cnorm[j]</i> must be greater than or equal to the 1-norm. |
| <i>work</i>  | (local).                                                                                                                                                                                                                                                                                                                                                                                                                               |

Temporary workspace.

## Output Parameters

|              |                                                                                                                                                                                                                                                                        |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>X</i>     | On exit, <i>x</i> is overwritten by the solution vector <i>x</i> .                                                                                                                                                                                                     |
| <i>scale</i> | Array of size <i>lDa</i> * <i>n</i> . The scaling factor <i>s</i> for the triangular system as described above.<br>If <i>scale</i> = 0, the matrix <i>A</i> is singular or badly scaled, and the vector <i>x</i> is an exact or approximate solution to <i>AX</i> = 0. |
| <i>cnorm</i> | If <i>normin</i> = 'N', <i>cnorm</i> is an output argument and <i>cnorm[j]</i> returns the 1-norm of the off-diagonal part of the ( <i>j</i> +1)-th column of <i>A</i> , <i>j</i> =0, 1, ..., <i>n</i> -1.                                                             |

## p?latrz

Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.

## Syntax

```
void pslatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work);
void pdlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work);
void pclatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work);
void pzlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work);
```

## Description

The p?latrz function reduces the *m*-by-*n* (*m* ≤ *n*) real/complex upper trapezoidal matrix *sub(A)* = [*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1) *A*(*ia*:*ia*+*m*-1, *ja*+*n*-1:*ja*+*n*-1)] to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix *sub(A)* is factored as

`sub(A) = ( R 0 ) * Z,`

where  $Z$  is an  $n$ -by- $n$  orthogonal/unitary matrix and  $R$  is an  $m$ -by- $m$  upper triangular matrix.

## Input Parameters

|                    |                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>m</code>     | (global)                                                                                                                                                                                                                                                         |
|                    | The number of rows in the distributed matrix $\text{sub}(A)$ . $m \geq 0$ .                                                                                                                                                                                      |
| <code>n</code>     | (global)                                                                                                                                                                                                                                                         |
|                    | The number of columns in the distributed matrix $\text{sub}(A)$ . $n \geq 0$ .                                                                                                                                                                                   |
| <code>l</code>     | (global)                                                                                                                                                                                                                                                         |
|                    | The number of columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. $l > 0$ .                                                                                                                          |
| <code>a</code>     | (local)                                                                                                                                                                                                                                                          |
|                    | Pointer into the local memory to an array of size $l\text{ld\_a} * \text{LOCc}(ja+n-1)$ . On entry, the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ , which is to be factored.                                                           |
| <code>ia</code>    | (global)                                                                                                                                                                                                                                                         |
|                    | The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$ .                                                                                                                                                                             |
| <code>ja</code>    | (global)                                                                                                                                                                                                                                                         |
|                    | The column index in the global matrix $A$ indicating the first column of $\text{sub}(A)$ .                                                                                                                                                                       |
| <code>desca</code> | (global and local) array of size $dlen_$ .                                                                                                                                                                                                                       |
|                    | The array descriptor for the distributed matrix $A$ .                                                                                                                                                                                                            |
| <code>work</code>  | (local)                                                                                                                                                                                                                                                          |
|                    | Workspace array of size $lwork$ .                                                                                                                                                                                                                                |

|                    | $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol),$                                                                                                                                                                                                      |
|                    | $mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow),$                                                                                                                                                                                                      |
|                    | $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npcol),$                                                                                                                                                                                                      |
|                    | <code>numroc</code> , <code>indxg2p</code> , and <code>numroc</code> are ScaLAPACK tool functions; <code>myrow</code> , <code>mycol</code> , <code>nprow</code> , and <code>npcol</code> can be determined by calling the function <code>blacs_gridinfo</code> . |

## Output Parameters

*a*

On exit, the leading  $m$ -by- $m$  upper triangular part of  $\text{sub}(A)$  contains the upper triangular matrix  $R$ , and elements  $n-l+1$  to  $n$  of the first  $m$  rows of  $\text{sub}(A)$ , with the array  $\tau$ , represent the orthogonal/unitary matrix  $Z$  as a product of  $m$  elementary reflectors.

*tau*

(local)

Array of size  $\text{LOCr}(ja+m-1)$ . This array contains the scalar factors of the elementary reflectors.  $\tau$  is tied to the distributed matrix  $A$ .

## Application Notes

The factorization is obtained by Householder's method. The  $k$ -th transformation matrix,  $Z(k)$ , which is used (or, in case of complex functions, whose conjugate transpose is used) to introduce zeros into the  $(m - k + 1)$ -th row of  $\text{sub}(A)$ , is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - \tau \cdot u(k) \cdot u(k)', \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

$\tau$  is a scalar and  $z(k)$  is an  $(n-m)$ -element vector.  $\tau$  and  $z(k)$  are chosen to annihilate the elements of the  $k$ -th row of  $\text{sub}(A)$ . The scalar  $\tau$  is returned in the  $k$ -th element of  $\tau$ , indexed  $k-1$ , and the vector  $u(k)$  in the  $k$ -th row of  $\text{sub}(A)$ , such that the elements of  $z(k)$  are in  $A(k, m+1), \dots, A(k, n)$ . The elements of  $R$  are returned in the upper triangular part of  $\text{sub}(A)$ .

$Z$  is given by

$$Z = Z(1) Z(2) \dots Z(m).$$

## p?lauu2

Computes the product  $U^*U'$  or  $L^*L$ , where  $U$  and  $L$  are upper or lower triangular matrices (local unblocked algorithm).

## Syntax

```
void pslauu2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
void pdlauu2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
void pclauu2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca);
```

```
void pzlauu2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lauu2` function computes the product  $U^*U'$  or  $L^*L$ , where the triangular factor  $U$  or  $L$  is stored in the upper or lower triangular part of the distributed matrix

`sub(A) = A(ia:ia+n-1, ja:ja+n-1).`

If `uplo = 'U'` or `'u'`, then the upper triangle of the result is stored, overwriting the factor  $U$  in `sub(A)`.

If `uplo = 'L'` or `'l'`, then the lower triangle of the result is stored, overwriting the factor  $L$  in `sub(A)`.

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#). No communication is performed by this function, the matrix to operate on should be strictly local to one process.

## Input Parameters

|                    |                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uplo</code>  | (global)                                                                                                                                    |
|                    | Specifies whether the triangular factor stored in the <i>matrix</i> <code>sub(A)</code> is upper or lower triangular:                       |
|                    | = <code>U</code> : upper triangular                                                                                                         |
|                    | = <code>L</code> : lower triangular.                                                                                                        |
| <code>n</code>     | (global)                                                                                                                                    |
|                    | The number of rows and columns to be operated on, that is, the order of the triangular factor $U$ or $L$ . $n \geq 0$ .                     |
| <code>a</code>     | (local)                                                                                                                                     |
|                    | Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$ . On entry, the local pieces of the triangular factor $U$ or $L$ . |
| <code>ia</code>    | (global)                                                                                                                                    |
|                    | The row index in the global matrix $A$ indicating the first row of <code>sub(A)</code> .                                                    |
| <code>ja</code>    | (global)                                                                                                                                    |
|                    | The column index in the global matrix $A$ indicating the first column of <code>sub(A)</code> .                                              |
| <code>desca</code> | (global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .                                 |

## Output Parameters

|                |                                                                                                                                                                                                                                                                                                              |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a</code> | (local)                                                                                                                                                                                                                                                                                                      |
|                | On exit, if <code>uplo = 'U'</code> , the upper triangle of the distributed matrix <code>sub(A)</code> is overwritten with the upper triangle of the product $U^*U'$ ; if <code>uplo = 'L'</code> , the lower triangle of <code>sub(A)</code> is overwritten with the lower triangle of the product $L^*L$ . |

## p?lauum

Computes the product  $U^*U'$  or  $L'^*L$ , where  $U$  and  $L$  are upper or lower triangular matrices.

## Syntax

```
void pslauum (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
void pdlauum (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
void pclauum (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
void pzlaum (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca);
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?lauum` function computes the product  $U^*U'$  or  $L'^*L$ , where the triangular factor  $U$  or  $L$  is stored in the upper or lower triangular part of the matrix  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ .

If `uplo` = '`U`' or '`u`', then the upper triangle of the result is stored, overwriting the factor  $U$  in  $\text{sub}(A)$ . If `uplo` = '`L`' or '`l`', then the lower triangle of the result is stored, overwriting the factor  $L$  in  $\text{sub}(A)$ .

This is the blocked form of the algorithm, calling Level 3 PBLAS.

## Input Parameters

`uplo`

(global)

Specifies whether the triangular factor stored in the matrix  $\text{sub}(A)$  is upper or lower triangular:

- = '`U`': upper triangular
- = '`L`': lower triangular.

`n`

(global)

The number of rows and columns to be operated on, that is, the order of the triangular factor  $U$  or  $L$ .  $n \geq 0$ .

`a`

(local)

Pointer into the local memory to an array of size  $lld_a * LOCc(ja+n-1)$ . On entry, the local pieces of the triangular factor  $U$  or  $L$ .

`ia`

(global)

The row index in the global matrix  $A$  indicating the first row of  $\text{sub}(A)$ .

`ja`

(global)

The column index in the global matrix  $A$  indicating the first column of  $\text{sub}(A)$ .

*desca* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix  $A$ .

## Output Parameters

*a* (local)

On exit, if *uplo* = 'U', the upper triangle of the distributed matrix  $\text{sub}(A)$  is overwritten with the upper triangle of the product  $U^*U'$ ; if *uplo* = 'L', the lower triangle of  $\text{sub}(A)$  is overwritten with the lower triangle of the product  $L'^*L$ .

## See Also

## p?lawil

Forms the Wilkinson transform.

---

## Syntax

```
void pslawil (const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *m, const float *a,
const MKL_INT *desca, const float *h44, const float *h33, const float *h43h34, float
*v);

void pdlawil (const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *m, const double *a,
const MKL_INT *desca, const double *h44, const double *h33, const double *h43h34,
double *v);

void pclawil (const MKL_INT *ii , const MKL_INT *jj , const MKL_INT *m , const
MKL_Complex8 *a , const MKL_INT *desca , const MKL_Complex8 *h44 , const MKL_Complex8
*h33 , const MKL_Complex8 *h43h34 , MKL_Complex8 *v);

void pzlawil (const MKL_INT *ii , const MKL_INT *jj , const MKL_INT *m , const
MKL_Complex16 *a , const MKL_INT *desca , const MKL_Complex16 *h44 , const
MKL_Complex16 *h33 , const MKL_Complex16 *h43h34 , MKL_Complex16 *v);
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lawil function gets the transform given by  $h44$ ,  $h33$ , and  $h43h34$  into  $v$  starting at row  $m$ .

## Input Parameters

*ii* (global)

Number of the process row which owns the matrix element  $A(m+2, m+2)$ .

*jj* (global)

Number of the process column which owns the matrix element  $A(m+2, m+2)$ .

*m* (global)

On entry, the location from where the transform starts (row  $m$ ). Unchanged on exit.

$a$  (local)

Array of size  $l\!d\_a * LOCc(n\_a)$ .

On entry, the Hessenberg matrix. Unchanged on exit.

$desca$  (global and local)

Array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ . Unchanged on exit.

$h43h34$  (global)

These three values are for the double shift QR iteration. Unchanged on exit.

## Output Parameters

$v$  (global)

Array of size 3 that contains the transform on output.

## Description

The `p?org2r/p?ung2r` function generates an  $m$ -by- $n$  real/complex matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal columns, which is defined as the first  $n$  columns of a product of  $k$  elementary reflectors of order  $m$ :

$$Q = H(1)*H(2)*...*H(k)$$

as returned by [p?geqrf](#).

## Input Parameters

| <i>work</i>  | (local)<br>Workspace array of size <i>lwork</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>lwork</i> | (local or global)<br>The size of the array <i>work</i> .<br><i>lwork</i> is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$ , where<br>$\begin{aligned} iroffa &= \text{mod}(ia-1, mb\_a), \quad icoffa = \text{mod}(ja-1, nb\_a), \\ iarow &= \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow), \\ iacol &= \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol), \\ mpa0 &= \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow), \\ nqa0 &= \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcol). \end{aligned}$ |

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprov`, and `npcol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Description

The `p?orgl2/p?ungl2` function generates a  $m$ -by- $n$  real/complex matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal rows, which is defined as the first  $m$  rows of a product of  $k$  elementary reflectors of order  $n$ .

$Q = H(k)*...*H(2)*H(1)$  (for real flavors),

$Q = (H(k))^H*...*(H(2))^H*(H(1))^H$  (for complex flavors) as returned by [p?gelqf](#).

## Input Parameters

This array is tied to the distributed matrix $A$ .                                                                                                                                                                                                                                                         |
| $WORK$  | (local)<br>Workspace array of size $lwork$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| $lwork$ | (local or global)<br>The size of the array $work$ .<br>$lwork$ is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$ , where<br>$\begin{aligned}iroffa &= \text{mod}(ia-1, mb\_a), \\icoffa &= \text{mod}(ja-1, nb\_a), \\iarow &= \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow), \\iacol &= \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol), \\mpa0 &= \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow), \\nqa0 &= \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcol).\end{aligned}$ |

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprov`, and `npcol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

## Description

The `p?orgr2/p?ungr2` function generates an  $m$ -by- $n$  real/complex matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal rows, which is defined as the last  $m$  rows of a product of  $k$  elementary reflectors of order  $n$ .

$Q = H(1)*H(2)*...*H(k)$  (for real flavors);

$Q = (H(1))^H*(H(2))^H...*(H(k))^H$  (for complex flavors) as returned by [p?gerqf](#).

## Input Parameters

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Description

The p?orm2l/p?unm2lfunction overwrites the general real/complex  $m$ -by- $n$  distributed matrix sub  $(C)=C(ic:ic+m-1,jc:jc+n-1)$  with

$Q^* \text{sub}(C)$  if  $\text{side} = \text{'L'}$  and  $\text{trans} = \text{'N'}$ , or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$  if  $\text{side} = \text{'L'}$  and  $\text{trans} = \text{'T'}$  (for real flavors) or  $\text{trans} = \text{'C'}$  (for complex flavors), or

$\text{sub}(C)*Q$  if  $\text{side} = \text{'R'}$  and  $\text{trans} = \text{'N'}$ , or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$  if  $\text{side} = \text{'R'}$  and  $\text{trans} = \text{'T'}$  (for real flavors) or  $\text{trans} = \text{'C'}$  (for complex flavors).

where  $Q$  is a real orthogonal or complex unitary distributed matrix defined as the product of  $k$  elementary reflectors

$Q = H(k)*\dots*H(2)*H(1)$  as returned by [p?geqlf](#).  $Q$  is of order  $m$  if  $\text{side} = \text{'L'}$  and of order  $n$  if  $\text{side} = \text{'R'}$ .

## Input Parameters

`ilcm`, `indxg2p`, and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprov`, and `ncol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

|                   |                                                                                                                                                                                                                                                                                        |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>c</code>    | On exit, <code>c</code> is overwritten by $Q^* \text{sub}(C)$ , or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$ , or $\text{sub}(C) * Q$ , or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$                                                                                               |
| <code>work</code> | On exit, <code>work[0]</code> returns the minimal and optimal <code>lwork</code> .                                                                                                                                                                                                     |
| <code>info</code> | (local)<br>= 0: successful exit<br>< 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value,<br>then <code>info = - (i*100 + j)</code> ,<br>if the $i$ -th argument is a scalar and had an illegal value,<br>then <code>info = -i</code> . |

---

### NOTE

The distributed submatrices  $A_{(ia:*, ja:*)}$  and  $C_{(ic:ic+m-1, jc:jc+n-1)}$  must verify some alignment properties, namely the following expressions should be true:

If `side = 'L'`, (`mb_a == mb_c && iroffa == iroffc && iarow == icrow`)  
If `side = 'R'`, (`mb_a == nb_c && iroffa == iroffc`).

## Description

The p?orm2r/p?unm2r function overwrites the general real/complex  $m$ -by- $n$  distributed matrix sub  $(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

$Q^* \text{sub}(C)$  if  $\text{side} = 'L'$  and  $\text{trans} = 'N'$ , or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$  if  $\text{side} = 'L'$  and  $\text{trans} = 'T'$  (for real flavors) or  $\text{trans} = 'C'$  (for complex flavors), or

$\text{sub}(C)*Q$  if  $\text{side} = 'R'$  and  $\text{trans} = 'N'$ , or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$  if  $\text{side} = 'R'$  and  $\text{trans} = 'T'$  (for real flavors) or  $\text{trans} = 'C'$  (for complex flavors).

where  $Q$  is a real orthogonal or complex unitary matrix defined as the product of  $k$  elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$  as returned by p?geqrf.  $Q$  is of order  $m$  if  $\text{side} = 'L'$  and of order  $n$  if  $\text{side} = 'R'$ .

## Input Parameters

|              |                                                                                                  |
|--------------|--------------------------------------------------------------------------------------------------|
| <i>side</i>  | (global)                                                                                         |
|              | = ' <i>L</i> ': apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the left,  |
|              | = ' <i>R</i> ': apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the right. |
| <i>trans</i> | (global)                                                                                         |
|              | = ' <i>N</i> ': apply $Q$ (no transpose)                                                         |
|              | = ' <i>T</i> ': apply $Q^T$ (transpose, for real flavors)                                        |
|              | = ' <i>C</i> ': apply $Q^H$ (conjugate transpose, for complex flavors)                           |
| <i>m</i>     | (global)                                                                                         |
|              | The number of rows in the distributed matrix $\text{sub}(C)$ . $m \geq 0$ .                      |
| <i>n</i>     | (global)                                                                                         |
|              | The number of columns in the distributed matrix $\text{sub}(C)$ . $n \geq 0$ .                   |
| <i>k</i>     | (global)                                                                                         |
|              | The number of elementary reflectors whose product defines the matrix $Q$ .                       |
|              | If $\text{side} = 'L'$ , $m \geq k \geq 0$ ;                                                     |

*if side = 'R', n ≥ k ≥ 0.*

*a* (local)

Pointer into the local memory to an array of size  $lld_a * LOCc(ja+k-1)$ .

On entry, the  $j$ -th column of the matrix stored in *a* must contain the vector that defines the elementary reflector  $H(j)$ ,  $ja \leq j \leq ja+k-1$ , as returned by [p?geqrf](#) in the  $k$  columns of its distributed matrix argument  $A(ia:*, ja:ja+k-1)$ . The argument  $A(ia:*, ja:ja+k-1)$  is modified by the function but restored on exit.

*If side = 'L', lld\_a ≥ max(1, LOCr(ia+m-1)),*

*if side = 'R', lld\_a ≥ max(1, LOCr(ia+n-1)).*

*ia* (global)

The row index in the global matrix *A* indicating the first row of  $\text{sub}(A)$ .

*ja* (global)

The column index in the global matrix *A* indicating the first column of  $\text{sub}(A)$ .

*desca* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

*tau* (local)

Array of size  $LOCc(ja+k-1)$ . *tau[j]* contains the scalar factor of the elementary reflector  $H(j+1)$ ,  $j = 0, 1, \dots, LOCc(ja+k-1)-1$ , as returned by [p?geqrf](#). This array is tied to the distributed matrix *A*.

*c* (local)

Pointer into the local memory to an array of size  $lld_c * LOCc(jc+n-1)$ .

On entry, the local pieces of the distributed matrix  $\text{sub}(C)$ .

*ic* (global)

The row index in the global matrix *C* indicating the first row of  $\text{sub}(C)$ .

*jc* (global)

The column index in the global matrix *C* indicating the first column of  $\text{sub}(C)$ .

*descC* (global and local) array of size *dlen\_*.

The array descriptor for the distributed matrix *C*.

*work* (local)

Workspace array of size *lwork*.

*lwork* (local or global)

The size of the array *work*.

*lwork* is local input and must be at least

*if side = 'L', lwork ≥ mpc0 + max(1, nqc0),*

```

if side = 'R', lwork ≥ nqco + max(max(1, mpc0), numroc(numroc(n
+icooffc, nb_a, 0, 0, npcol), nb_a, 0, 0, lcmq)),
where
lcmq = lcm/npcol,
lcm = iclm(nprow, npcol),
iroffc = mod(ic-1, mb_c),
icooffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
Mqco = numroc(m+icooffc, nb_c, mycol, icrow, nprow),
Npc0 = numroc(n+iroffc, mb_c, myrow, iccol, npcol),
ilcm, indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npcol can be determined by calling the function
blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

## Output Parameters

|             |                                                                                                                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>c</i>    | On exit, <i>c</i> is overwritten by $Q^* \text{sub}(C)$ , or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$ , or $\text{sub}(C) * Q$ , or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$                                                                                                                                    |
| <i>work</i> | On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> .                                                                                                                                                                                                                                               |
| <i>info</i> | (local)<br>= 0: successful exit<br>< 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value,<br>then <i>info</i> = -( <i>i</i> *100 + <i>j</i> ),<br>if the <i>i</i> -th argument is a scalar and had an illegal value,<br>then <i>info</i> = - <i>i</i> . |

### NOTE

The distributed submatrices  $A_{(ia:*, ja:*)}$  and  $C_{(ic:ic+m-1, jc:jc+n-1)}$  must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*mb\_a* == *mb\_c*) && (*iroffa* == *iroffc*) && (*iarow* == *icrow*).  
If *side* = 'R', (*mb\_a* == *nb\_c*) && (*iroffa* == *iroffc*).

|              | The size of the array <i>work</i> .<br><i>lwork</i> is local input and must be at least<br><br>$\text{if } side = 'L', lwork \geq mqc0 + \max(\max(1, npc0), \text{numroc}(\text{numroc}(m + iroffc, mb_a, 0, 0, nprow), mb_a, 0, 0, lcm)) ,$ $\text{if } side = 'R', lwork \geq npc0 + \max(1, mqc0) ,$ <p>where</p> $lcm = lcm / nprow,$ $lcm = iclm(nprow, npcol),$ $iroffc = \text{mod}(ic-1, mb_c),$ $icooffc = \text{mod}(jc-1, nb_c),$ $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$ $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol),$ $Mpc0 = \text{numroc}(m + iroffc, mb_c, mycol, icrow, nprow),$ $Nqc0 = \text{numroc}(n + iroffc, nb_c, myrow, iccol, npcol),$ <p><i>ilcm</i>, <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i>, <i>mycol</i>, <i>nprow</i>, and <i>npcol</i> can be determined by calling the function <i>blacs_gridinfo</i>.</p> <p>If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <a href="#">pxerbla</a>.</p> |

## Output Parameters

|             |                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>c</i>    | On exit, <i>c</i> is overwritten by $Q * \text{sub}(C)$ , or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$ , or $\text{sub}(C) * Q$ , or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$                            |
| <i>work</i> | On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> .                                                                                                                                       |
| <i>info</i> | (local)<br>= 0: successful exit<br>< 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value,<br>then <i>info</i> = - ( <i>i</i> *100 + <i>j</i> ), |

---

if the  $i$ -th argument is a scalar and had an illegal value,  
then  $\text{info} = -i$ .

---

**NOTE**

The distributed submatrices  $A_{(ia:*, ja:*)}$  and  $C_{(ic:ic+m-1, jc:jc+n-1)}$  must verify some alignment properties, namely the following expressions should be true:

```
If side = 'L', (nb_a == mb_c && icoffa == iroffc)
If side = 'R', (nb_a == nb_c && icoffa == icoffc && iacol == iccol).
```

---

**Description**

The p?ormr2/p?unmr2function overwrites the general real/complex  $m$ -by- $n$  distributed matrix sub  $(C)=C_{(ic:ic+m-1, jc:jc+n-1)}$  with

$Q^*\text{sub}(C)$  if  $\text{side} = 'L'$  and  $\text{trans} = 'N'$ , or

$Q^T\text{sub}(C) / Q^H\text{sub}(C)$  if  $\text{side} = 'L'$  and  $\text{trans} = 'T'$  (for real flavors) or  $\text{trans} = 'C'$  (for complex flavors), or

$\text{sub}(C)*Q$  if  $\text{side} = 'R'$  and  $\text{trans} = 'N'$ , or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$  if  $\text{side} = 'R'$  and  $\text{trans} = 'T'$  (for real flavors) or  $\text{trans} = 'C'$  (for complex flavors).

where  $Q$  is a real orthogonal or complex unitary distributed matrix defined as the product of  $k$  elementary reflectors

$Q = H(1)*H(2)*...*H(k)$  (for real flavors)

$Q = (H(1))^H*(H(2))^H*...*(H(k))^H$  (for complex flavors)

as returned by `p?gerqf`.  $Q$  is of order  $m$  if `side` = '`L`' and of order  $n$  if `side` = '`R`'.

|                    | The row index in the global matrix $A$ indicating the first row of <code>sub(A)</code> .                                                                                                                                                                                        |
| <code>ja</code>    | (global)                                                                                                                                                                                                                                                                        |

The column index in the global matrix  $A$  indicating the first column of  $\text{sub}(A)$ .

*descA* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix  $A$ .

*tau* (local)

Array of size  $\text{LOCc}(ia+k-1)$ . *tau*[*j*] contains the scalar factor of the elementary reflector  $H(j+1), j = 0, 1, \dots, \text{LOCc}(ja+k-1)-1$ , as returned by [p?gerqf](#). This array is tied to the distributed matrix  $A$ .

*c* (local)

Pointer into the local memory to an array of size *lld\_c* \*  $\text{LOCc}(jc+n-1)$ . On entry, the local pieces of the distributed matrix  $\text{sub}(C)$ .

*ic* (global)

The row index in the global matrix  $C$  indicating the first row of  $\text{sub}(C)$ .

*jc* (global)

The column index in the global matrix  $C$  indicating the first column of  $\text{sub}(C)$ .

*descC* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix  $C$ .

*work* (local)

Workspace array of size *lwork*.

*lwork* (local or global)

The size of the array *work*.

*lwork* is local input and must be at least

```

if side = 'L', lwork ≥ mpc0 + max(max(1, nqc0), numroc(numroc(m
+iroffc, mb_a, 0, 0, nprow), mb_a, 0, 0, lcm),
if side = 'R', lwork ≥ nqc0 + max(1, mpc0),
where lcm = lcm(nprow, npcol),
lcm = iclm(nprow, npcol),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
Mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow),
Nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npcol),
ilcm, indxg2p and numroc are ScalAPACK tool functions; myrow, mycol,
nprow, and npcol can be determined by calling the function
blacs_gridinfo.
```

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

## Output Parameters

|        |                                                                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $c$    | On exit, $c$ is overwritten by $Q^* \text{sub}(C)$ , or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$ , or $\text{sub}(C) * Q$ , or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$                                                                                   |
| $work$ | On exit, $work[0]$ returns the minimal and optimal $lwork$ .                                                                                                                                                                                                    |
| $info$ | (local)<br>= 0: successful exit<br>< 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value,<br>then $info = -(i*100 + j)$ ,<br>if the $i$ -th argument is a scalar and had an illegal value,<br>then $info = -i$ . |

---

### NOTE

The distributed submatrices  $A_{(ia:*, ja:*)}$  and  $C_{(ic:ic+m-1, jc:jc+n-1)}$  must verify some alignment properties, namely the following expressions should be true:

If  $side = 'L'$ ,  $(nb_a == mb_c) \&& (icoffa == iroffc)$ .

If  $side = 'R'$ ,  $(nb_a == nb_c) \&& (icoffa == icoffc) \&& (iacol == iccol)$ .

## Description

The `p?pbtrs` function solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where  $A(1:n, ja:ja+n-1)$  is a banded triangular matrix factor produced by the Cholesky factorization code `p?pbtrf` and is stored in  $A(1:n, ja:ja+n-1)$  and  $af$ . The matrix stored in  $A(1:n, ja:ja+n-1)$  is either upper or lower triangular according to `uplo`.

The function `p?pbtrf` must be called first.

### Product and Performance Information

## Application Notes

If the factorization function and the solve function are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space *af* must not be altered between calls to the factorization function and the solve function.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case  $N/P \gg bw$  are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix *A* one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into *P* pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

- Local Phase:** The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space *af*. Mathematically, this is equivalent to reordering the matrix *A* as  $PAP^T$  and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of *A* in memory.
- Reduced System Phase:** A small ( $bw^*(P-1)$ ) system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space *af*. A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
- Back Substitution Phase:** For a linear system, a local backsubstitution is performed on each processor in parallel.

### Description

The p?pttrsvfunction solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where  $A(1:n, ja:ja+n-1)$  is a tridiagonal triangular matrix factor produced by the Cholesky factorization code p?pttrf and is stored in  $A(1:n, ja:ja+n-1)$  and af. The matrix stored in  $A(1:n, ja:ja+n-1)$  is either upper or lower triangular according to uplo.

The function p?pttrf must be called first.

### Input Parameters

|       |                                                                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| uplo  | (global) Must be 'U' or 'L'.<br><br>If uplo = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;<br>If uplo = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.                 |
| trans | (global) Must be 'N' or 'C'.<br><br>If trans = 'N', solve with $A(1:n, ja:ja+n-1)$ ;<br>If trans = 'C' (for complex flavors), solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$ . |

|              |                                                                                                                                                                                                                                                                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>     | (global)                                                                                                                                                                                                                                                                                                                                      |
|              | The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ . $n \geq 0$ .                                                                                                                                                                                                          |
| <i>nrhs</i>  | (global)                                                                                                                                                                                                                                                                                                                                      |
|              | The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$ ; $nrhs \geq 0$ .                                                                                                                                                                                                                   |
| <i>d</i>     | (local)                                                                                                                                                                                                                                                                                                                                       |
|              | Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size $\geq nb\_a$ .                                                                                                                                                                                                                        |
| <i>e</i>     | (local)                                                                                                                                                                                                                                                                                                                                       |
|              | Pointer to the local part of the global vector $du$ storing the upper diagonal of the matrix; must be of size $\geq nb\_a$ . Globally, $du(n)$ is not referenced, and $du$ must be aligned with $d$ .                                                                                                                                         |
| <i>ja</i>    | (global) The index in the global matrix $A$ that points to the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).                                                                                                                                                                                 |
| <i>desca</i> | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .<br><br>If 1D type ( $dtype\_a = 501$ or $502$ ), then $dlen \geq 7$ ;<br>If 2D type ( $dtype\_a = 1$ ), then $dlen \geq 9$ .<br><br>Contains information on mapping of $A$ to memory. See ScaLAPACK manual for full description and options. |
| <i>b</i>     | (local)<br><br>Pointer into the local memory to an array of local lead size $lld\_b \geq nb$ .<br><br>On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$ .                                                                                                                                         |
| <i>ib</i>    | (global) The row index in the global matrix $B$ that points to the first row of the matrix to be operated on (which may be either all of $B$ or a submatrix of $B$ ).                                                                                                                                                                         |
| <i>descb</i> | (global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $B$ .<br><br>If 1D type ( $dtype\_b = 502$ ), then $dlen \geq 7$ ;<br>If 2D type ( $dtype\_b = 1$ ), then $dlen \geq 9$ .<br><br>Contains information on mapping of $B$ to memory. See ScaLAPACK manual for full description and options.          |
| <i>laf</i>   | (local)<br><br>The size of user-input auxiliary fill-in space $af$ . Must be $laf \geq (nb + 2 * bw) * bw$ .<br><br>If $laf$ is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$ .                                                                                                |
| <i>work</i>  | (local)                                                                                                                                                                                                                                                                                                                                       |

The array `work` is a temporary workspace array of size `lwork`. This space may be overwritten in between function calls.

`lwork`

(local or global) The size of the user-input workspace `work`, must be at least  $lwork \geq (10 + 2 * \min(100, nrhs)) * n_{pcol} + 4 * nrhs$ . If `lwork` is too small, the minimal acceptable size will be returned in `work[0]` and an error code is returned.

## Output Parameters

`d, e`

(local).

On exit, these arrays contain information on the factors of the matrix.

`af`

(local)

The array `af` is of size `laf`. It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?pbtrf` and is stored in `af`. If a linear system is to be solved using `p?pttrs` after the factorization function, `af` must not be altered after the factorization.

`b`

On exit, this array contains the local piece of the solutions distributed matrix  $X$ .

`work[0]`

On exit, `work[0]` contains the minimum value of `lwork`.

`info`

(local)

= 0: successful exit

< 0: if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value,

then `info = - (i * 100 + j)`,

if the  $i$ -th argument is a scalar and had an illegal value,

then `info = -i`.

## `p?potf2`

Computes the Cholesky factorization of a symmetric/  
Hermitian positive definite matrix (local unblocked  
algorithm).

---

## Syntax

```
void pspotf2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *info);
void pdpotf2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *info);
void pcpotf2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info);
void pzpotf2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?potf2` function computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ .

The factorization has the form

$$\text{sub}(A) = U^*U, \text{ if } \text{uplo} = 'U', \text{ or } \text{sub}(A) = L*L', \text{ if } \text{uplo} = 'L',$$

where  $U$  is an upper triangular matrix,  $L$  is lower triangular.  $X'$  denotes transpose (conjugate transpose) of  $X$ .

## Input Parameters

`uplo`

(global)

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix  $A$  is stored.

= 'U': upper triangle of  $\text{sub}(A)$  is stored;

= 'L': lower triangle of  $\text{sub}(A)$  is stored.

`n`

(global)

The number of rows and columns to be operated on, that is, the order of the distributed matrix  $\text{sub}(A)$ .  $n \geq 0$ .

`a`

(local)

Pointer into the local memory to an array of size  $lld_a * LOCc(ja+n-1)$  containing the local pieces of the  $n$ -by- $n$  symmetric distributed matrix  $\text{sub}(A)$  to be factored.

If  $\text{uplo} = 'U'$ , the leading  $n$ -by- $n$  upper triangular part of  $\text{sub}(A)$  contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced.

If  $\text{uplo} = 'L'$ , the leading  $n$ -by- $n$  lower triangular part of  $\text{sub}(A)$  contains the lower triangular matrix and the strictly upper triangular part of  $\text{sub}(A)$  is not referenced.

`ia, ja`

(global)

The row and column indices in the global matrix  $A$  indicating the first row and the first column of the  $\text{sub}(A)$ , respectively.

`desca`

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

## Output Parameters

`a`

(local)

On exit,

if  $\text{uplo} = 'U'$ , the upper triangular part of the distributed matrix contains the Cholesky factor  $U$ ;

if  $\text{uplo} = 'L'$ , the lower triangular part of the distributed matrix contains the Cholesky factor  $L$ .

*info* (local)

- = 0: successful exit
- < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,  
then *info* = - (*i*\*100 +*j*),
- if the *i*-th argument is a scalar and had an illegal value,  
then *info* = -*i*.
- > 0: if *info* = *k*, the leading minor of order *k* is not positive definite, and  
the factorization could not be completed.

## p?rot

Applies a planar rotation to two distributed vectors.

### Syntax

```
void psrot(MKL_INT* n, float* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT* incx, float* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, float* cs, float* sn, float* work, MKL_INT* lwork, MKL_INT* info);

void pdrot(MKL_INT* n, double* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT* incx, double* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, double* cs, double* sn, double* work, MKL_INT* lwork, MKL_INT* info);
```

### Include Files

- mkl\_scalapack.h

### Description

p?rot applies a planar rotation defined by *cs* and *sn* to the two distributed vectors sub(*x*) and sub(*y*).

### Input Parameters

*n* (global )  
The number of elements to operate on when applying the planar rotation to *x* and *y* (*n*≥0).

*x* (local) array of size ( (*jx*-1)\**m\_x* + *ix* + ( *n* - 1 )\*abs( *incx* ) )  
This array contains the entries of the distributed vector sub( *x* ).

*ix* (global )  
The global row index of the submatrix of the distributed matrix *x* to operate on. If *incx* = 1, then it is required that *ix* = *iy*. 1 ≤ *ix* ≤ *m\_x*.

*jx* (global )  
The global column index of the submatrix of the distributed matrix *x* to operate on. If *incx* = *m\_x*, then it is required that *jx* = *jy*. 1 ≤ *jx* ≤ *n\_x*.

*descx* (global and local) array of size 9

The array descriptor of the distributed matrix  $x$ .

$incx$

(global )

The global increment for the elements of  $x$ . Only two values of  $incx$  are supported in this version, namely 1 and  $m_x$ . Moreover, it must hold that  $incx = m_x$  if  $incy = m_y$  and that  $incx = 1$  if  $incy = 1$ .

$y$

(local) array of size (  $(jy-1)*m_y + iy + (n - 1)*abs(incy)$  )

This array contains the entries of the distributed vector sub(  $y$  ).

$i_y$

(global )

The global row index of the submatrix of the distributed matrix  $y$  to operate on. If  $incy = 1$ , then it is required that  $i_y = ix$ .  $1 \leq i_y \leq m_y$ .

$j_y$

(global )

The global column index of the submatrix of the distributed matrix  $y$  to operate on. If  $incy = m_x$ , then it is required that  $j_y = jx$ .  $1 \leq j_y \leq m_y$ .

$descy$

(global and local) array of size 9

The array descriptor of the distributed matrix  $y$ .

$incy$

(global )

The global increment for the elements of  $y$ . Only two values of  $incy$  are supported in this version, namely 1 and  $m_y$ . Moreover, it must hold that  $incy = m_y$  if  $incx = m_x$  and that  $incy = 1$  if  $incx = 1$ .

$cs, sn$

(global)

The parameters defining the properties of the planar rotation. It must hold that  $0 \leq cs, sn \leq 1$  and that  $sn^2 + cs^2 = 1$ . The latter is hardly checked in finite precision arithmetics.

$work$

(local workspace) array of size  $lwork$

$lwork$

(local )

The length of the workspace array  $work$ .

If  $incx = 1$  and  $incy = 1$ , then  $lwork = 2*m_x$

If  $lwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the  $work$  array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by [pxerbla](#).

## OUTPUT Parameters

$x$

$y$

$work[0]$

On exit, if  $info = 0$ ,  $work[0]$  returns the optimal  $lwork$

$info$

(global )

= 0: successful exit

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value.

If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $\text{info} = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $\text{info} = -i$ .

## See Also

- mkl\_scalapack.h

## Description

The p?rscl function multiplies an  $n$ -element real/complex vector  $\text{sub}(X)$  by the real scalar  $1/a$ . This is done without overflow or underflow as long as the final result  $\text{sub}(X)/a$  does not overflow or underflow.

$\text{sub}(X)$  denotes  $X(ix:ix+n-1, jx:jx)$ , if  $\text{incx} = 1$ ,

and  $X(ix:ix, jx:jx+n-1)$ , if  $\text{incx} = \underline{m\_x}$ .

## Input Parameters

|         |                    |                                                                                                                                                                                                                       |
|---------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $n$     | (global)           | The number of components of the distributed vector $\text{sub}(X)$ . $n \geq 0$ .                                                                                                                                     |
| $sa$    |                    | The scalar $a$ that is used to divide each component of the vector $\text{sub}(X)$ . This parameter must be $\geq 0$ .                                                                                                |
| $sx$    |                    | Array containing the local pieces of a distributed matrix of size of at least $((jx-1)*\underline{m\_x} + ix + (n-1)*\text{abs}(incx))$ . This array contains the entries of the distributed vector $\text{sub}(X)$ . |
| $ix$    | (global)           | The row index of the submatrix of the distributed matrix $X$ to operate on.                                                                                                                                           |
| $jx$    | (global)           | The column index of the submatrix of the distributed matrix $X$ to operate on.                                                                                                                                        |
| $descx$ | (global and local) | Array of size 9. The array descriptor for the distributed matrix $X$ .                                                                                                                                                |

*incx* (global)  
 The increment for the elements of *X*. This version supports only two values of *incx*, namely 1 and *m\_x*.

## Output Parameters

*sx* On exit, the result *x/a*.

## Description

The p?sygs2/p?hegs2function reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

Here  $\text{sub}(A)$  denotes  $A(ia:ia+n-1, ja:ja+n-1)$ , and  $\text{sub}(B)$  denotes  $B(ib:ib+n-1, jb:jb+n-1)$ .

If *ibtype* = 1, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$$

and  $\text{sub}(A)$  is overwritten by

$\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$  or  $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$  - for real flavors, and

$\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$  or  $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$  - for complex flavors.

If *ibtype* = 2 or 3, the problem is

$$\text{sub}(A) * \text{sub}(B) x = \lambda * x \text{ or } \text{sub}(B) * \text{sub}(A) x = \lambda * x$$

and  $\text{sub}(A)$  is overwritten by

$U^* \text{sub}(A) * U^T$  or  $L^* \text{sub}(A) * L^T$  for real flavors and

$U^* \text{sub}(A) * U^H$  or  $L^* \text{sub}(A) * L^H$  for complex flavors.

The matrix  $\text{sub}(B)$  must have been previously factorized as  $U^T * U$  or  $L^* L^T$  (for real flavors), or as  $U^H * U$  or  $L^* L^H$  (for complex flavors) by [p?potrf](#).

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of  $\text{sub}(B)$  as returned by [p?potrf](#).

*ib, jb*

(global)

The row and column indices in the global matrix  $B$  indicating the first row and the first column of the  $\text{sub}(B)$ , respectively.

*descb*

(global and local) array of size *dlen\_*. The array descriptor for the distributed matrix  $B$ .

## Output Parameters

*a*

(local)

On exit, if *info* = 0, the transformed matrix is stored in the same format as  $\text{sub}(A)$ .

*info*

= 0: successful exit.

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,

then *info* = -(*i*\*100+*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

## Description

The p?syt2/p?hetd2 function reduces a real symmetric/complex Hermitian matrix  $\text{sub}(A)$  to symmetric/Hermitian tridiagonal form  $T$  by an orthogonal/unitary similarity transformation:

$Q' * \text{sub}(A) * Q = T$ , where  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ .

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

The diagonal elements of the tridiagonal matrix<br>$T$ :                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

$d[i] = A(i+1,i+1)$ , where  $i=0,1, \dots, LOCc(ja+n-1) - 1$ ;  $d$  is tied to the distributed matrix  $A$ .

$e$  (local)

Array of size  $LOCc(ja+n-1)$ ,  
if  $uplo = 'U'$ ,  $LOCc(ja+n-2)$  otherwise.

The off-diagonal elements of the tridiagonal matrix  $T$ :

$e[i] = A(i+1,i+2)$  if  $uplo = 'U'$ ,  
 $e[i] = A(i+2,i+1)$  if  $uplo = 'L'$ ,  
where  $i=0,1, \dots, LOCc(ja+n-1) - 1$ .

$e$  is tied to the distributed matrix  $A$ .

$\tau_{au}$  (local)

Array of size  $LOCc(ja+n-1)$ .

The scalar factors of the elementary reflectors.  $\tau_{au}$  is tied to the distributed matrix  $A$ .

$\text{work}[0]$

On exit,  $\text{work}[0]$  returns the minimal and optimal value of  $\text{lwork}$ .

$\text{lwork}$

(local or global)

The size of the workspace array  $\text{work}$ .

$\text{lwork}$  is local input and must be at least  $\text{lwork} \geq 3n$ .

If  $\text{lwork} = -1$ , then  $\text{lwork}$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

$\text{info}$  (local)

= 0: successful exit

< 0: if the  $i$ -th argument, indexed  $i-1$ , is an array and the  $j$ -th entry had an illegal value,

then  $\text{info} = -(i*100+j)$ ,

if the  $i$ -th argument is a scalar and had an illegal value,

then  $\text{info} = -i$ .

## Application Notes

If  $uplo = 'U'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1)$$

Each  $H(i)$  has the form

$$H(i) = I - \tau_{au} * v * v^T,$$

where  $\tau_{au}$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(i+1:n) = 0$  and  $v(i) = 1$ ;  $v(1:i-1)$  is stored on exit in  $A(ia:ia+i-2, ja+i)$ , and  $\tau_{au}$  in  $\tau_{au}[ja+i-2]$ .

If  $uplo = 'L'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$Q = H(1)*H(2)*\dots*H(n-1)$ .

Each  $H(i)$  has the form

$H(i) = I - \tau u^* v^* v'$ ,

where  $\tau u$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i) = 0$  and  $v(i+1) = 1$ ;  $v(i+2:n)$  is stored on exit in  $A(ia+i+1:ia+n-1, ja+i-1)$ , and  $\tau u$  in  $\tau u[ja+i-2]$ .

The contents of sub ( $A$ ) on exit are illustrated by the following examples with  $n = 5$ :

|                                                                                                                               |                                                                                                                               |
|-------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>if <math>uplo='U'</math>:</b>                                                                                              | <b>if <math>uplo='L'</math>:</b>                                                                                              |
| $\begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{bmatrix}$ | $\begin{bmatrix} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{bmatrix}$ |

where  $d$  and  $e$  denotes diagonal and off-diagonal elements of  $T$ , and  $v_i$  denotes an element of the vector defining  $H(i)$ .

### NOTE

The distributed matrix sub( $A$ ) must verify some alignment properties, namely the following expression should be true:

(  $mb\_a == nb\_a \&& iroffa == icoffa$  ) where  $iroffa = \text{mod}(ia - 1, mb\_a)$  and  $icoffa = \text{mod}(ja - 1, nb\_a)$ .

### Description

p?trord reorders the real Schur factorization of a real matrix  $A = Q*T^*Q^T$ , so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix  $T$ , and the leading columns of  $Q$  form an orthonormal basis of the corresponding right invariant subspace.

$T$  must be in Schur form (as returned by [p?lahqr](#)), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

This function uses a delay and accumulate procedure for performing the off-diagonal updates.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

|               | <i>para[2]</i> window size; $para[1] < para[2] < mb\_t$ must hold;                                                                                                                                                                                                                                                                                                                                                          |
|               | <i>para[3]</i> minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para[3] \leq 100$ must hold;                                                                                                                                                                                                                                      |
|               | <i>para[4]</i> width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para[4] \leq mb\_t$ must hold.                                                                                                                                                                                                                                                   |
|               | <i>para[5]</i> the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; $0 < para[5] \leq para[1]$ must hold.                                                                                                                                                                                                                  |
| <i>n</i>      | (global)                                                                                                                                                                                                                                                                                                                                                                                                                    |

The order of the globally distributed matrix  $t$ .  $n \geq 0$ .

$t$  (local) array of size  $\text{lld}_t * \text{LOC}_c(n)$ .

The local pieces of the global distributed upper quasi-triangular matrix  $T$ , in Schur form.

$it, jt$  (global)

The row and column index in the global matrix  $T$  indicating the first column of  $T$ .  $it = jt = 1$  must hold (see Application Notes).

$desc_t$  (global and local) array of size  $dlen_*$ .

The array descriptor for the global distributed matrix  $T$ .

$q$  (local) array of size  $\text{lld}_q * \text{LOC}_c(n)$ .

On entry, if  $\text{compq} = 'V'$ , the local pieces of the global distributed matrix  $Q$  of Schur vectors.

If  $\text{compq} = 'N'$ ,  $q$  is not referenced.

$iq, jq$  (global)

The column index in the global matrix  $Q$  indicating the first column of  $Q$ .  $iq = jq = 1$  must hold (see Application Notes).

$desc_q$  (global and local) array of size  $dlen_*$ .

The array descriptor for the global distributed matrix  $Q$ .

$work$  (local workspace) array of size  $lwork$

$lwork$  (local)

The size of the array  $work$ .

If  $lwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the  $work$  array, returns this value as the first entry of the  $work$  array, and no error message related to  $lwork$  is issued by [pxerbla](#).

$iwork$  (local workspace) array of size  $liwork$

$liwork$  (local)

The size of the array  $iwork$ .

If  $liwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the  $iwork$  array, returns this value as the first entry of the  $iwork$  array, and no error message related to  $liwork$  is issued by [pxerbla](#)

## OUTPUT Parameters

$select$  (global) array of size  $n$

The (partial) reordering is displayed.

$t$  On exit,  $t$  is overwritten by the local pieces of the reordered matrix  $T$ , again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.

*q*  
On exit, if *compq* = 'V', *q* has been postmultiplied by the global orthogonal transformation matrix which reorders *t*; the leading *m* columns of *q* form an orthonormal basis for the specified invariant subspace.

If *compq* = 'N', *q* is not referenced.

*wr, wi*  
(global ) array of size *n*

The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix *T*. The eigenvalues are in principle stored in the same order as on the diagonal of *T*, with *wr*[*i*] = *T*(*i*+1, *i*+1) and, if *T*(*i*:*i*+1, *i*:*i*+1) is a 2-by-2 diagonal block, *wi*[*i*-1] > 0 and *wi*[*i*] = -*wi*[*i*-1].

Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

*m*  
(global )

The size of the specified invariant subspace.

$0 \leq m \leq n$ .

*work*[0]  
On exit, if *info* = 0, *work*[0] returns the optimal *lwork*.

*iwork*[0]  
On exit, if *info* = 0, *iwork*[0] returns the optimal *liwork*.

*info*  
(global)

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value. If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = -(*i*\*1000+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

> 0: here we have several possibilities

- Reordering of *t* failed because some eigenvalues are too close to separate (the problem is very ill-conditioned);

*t* may have been partially reordered, and *wr* and *wi* contain the eigenvalues in the same order as in *t*.

On exit, *info* = {the index of *t* where the swap failed (indexing starts at 1)}.

- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

On exit, *info* = {the index of *t* where the swap failed}.

- If *info* = *n*+1, there is no valid BLACS context (see the BLACS documentation for details).

## Application Notes

The following alignment requirements must hold:

- *mb\_t* = *nb\_t* = *mb\_q* = *nb\_q*
- *rsrc\_t* = *rsrc\_q*
- *csrc\_t* = *csrc\_q*

All matrices must be blocked by a block factor larger than or equal to two (3). This is to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of  $t$  and  $q$ , i.e.,  $it = jt = iq = jq = 1$  must hold. This is however no limitation since [p?lahqr](#) does not compute Schur forms of submatrices anyway.

Parallel execution recommendations:

- Use a square grid, if possible, for maximum performance. The block parameters in *para* should be kept well below the data distribution block size.
- In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

## Description

`p?trsen` reorders the real Schur factorization of a real matrix  $A = Q*T*Q^T$ , so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix  $T$ , and the leading columns of  $Q$  form an orthonormal basis of the corresponding right invariant subspace. The reordering is performed by [p?trord](#).

Optionally the function computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

$T$  must be in Schur form (as returned by [p?lahqr](#)), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

|            |           |
|------------|-----------|
| <i>job</i> | (global ) |
|------------|-----------|

Specifies whether condition numbers are required for the cluster of eigenvalues ( $s$ ) or the invariant subspace ( $sep$ ):

- = 'N': no condition numbers are required;
- = 'E': only the condition number for the cluster of eigenvalues is computed ( $s$ );
- = 'V': only the condition number for the invariant subspace is computed ( $sep$ );
- = 'B': condition numbers for both the cluster and the invariant subspace are computed ( $s$  and  $sep$ ).

*compq*

- (global )  
 = 'V': update the matrix  $q$  of Schur vectors;  
 = 'N': do not update  $q$ .

*select*

*select* specifies the eigenvalues in the selected cluster. To select a real eigenvalue  $w(j)$ ,  $select[j-1]$  must be set to a non-zero number. To select a complex conjugate pair of eigenvalues  $w(j)$  and  $w(j+1)$ , corresponding to a 2-by-2 diagonal block, either  $select[j-1]$  or  $select[j]$  or both must be set to a non-zero number; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

*para*

(global )  
 Block parameters:

|                 |                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>para</i> [0] | maximum number of concurrent computational windows allowed in the algorithm; $0 < para[0] \leq \min(NPROW, NPCOL)$ must hold;                                                              |
| <i>para</i> [1] | number of eigenvalues in each window; $0 < para[1] < para[2]$ must hold;                                                                                                                   |
| <i>para</i> [2] | window size; $para[1] < para[2] < mb_t$ must hold;                                                                                                                                         |
| <i>para</i> [3] | minimal percentage of flops required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para[3] \leq 100$ must hold;                    |
| <i>para</i> [4] | width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para[4] \leq mb_t$ must hold.                                  |
| <i>para</i> [5] | the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size $0 < para[5] \leq para[1]$ must hold; |

*n*

(global )

The order of the globally distributed matrix  $t$ .  $n \geq 0$ .

|               |                                                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>t</i>      | (local ) array of size $lId\_t * LOC_c(n)$ .<br>The local pieces of the global distributed upper quasi-triangular matrix $T$ , in Schur form.                                                                                                                                                                                            |
| <i>it, jt</i> | (global )<br>The row and column index in the global matrix $T$ indicating the first column of $T$ . $it = jt = 1$ must hold (see Application Notes).                                                                                                                                                                                     |
| <i>descT</i>  | (global and local) array of size $dlen_$ .<br>The array descriptor for the global distributed matrix $T$ .                                                                                                                                                                                                                               |
| <i>q</i>      | (local ) array of size $lId\_q * LOC_c(n)$ .<br>On entry, if $compq = 'V'$ , the local pieces of the global distributed matrix $Q$ of Schur vectors.<br>If $compq = 'N'$ , <i>q</i> is not referenced.                                                                                                                                   |
| <i>iq, jq</i> | (global )<br>The column index in the global matrix $Q$ indicating the first column of $Q$ . $iq = jq = 1$ must hold (see Application Notes).                                                                                                                                                                                             |
| <i>descQ</i>  | (global and local) array of size $dlen_$ .<br>The array descriptor for the global distributed matrix $Q$ .                                                                                                                                                                                                                               |
| <i>work</i>   | (local workspace) array of size $lwork$                                                                                                                                                                                                                                                                                                  |
| <i>lwork</i>  | (local )<br>The size of the array <i>work</i> .<br>If $lwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <a href="#">pxerbla</a> .      |
| <i>iwork</i>  | (local workspace) array of size $liwork$                                                                                                                                                                                                                                                                                                 |
| <i>liwork</i> | (local )<br>The size of the array <i>iwork</i> .<br>If $liwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued by <a href="#">pxerbla</a> . |

## OUTPUT Parameters

|          |                                                                                                                                                                                                                                                |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>t</i> | <i>t</i> is overwritten by the local pieces of the reordered matrix $T$ , again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.                                                                          |
| <i>q</i> | On exit, if $compq = 'V'$ , <i>q</i> has been postmultiplied by the global orthogonal transformation matrix which reorders <i>t</i> ; the leading <i>m</i> columns of <i>q</i> form an orthonormal basis for the specified invariant subspace. |

If  $\text{compq} = \text{'N'}$ ,  $q$  is not referenced.

$\text{wr}, \text{wi}$

The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix  $T$ . The eigenvalues are in principle stored in the same order as on the diagonal of  $T$ , with  $\text{wr}[i] = T(i+1,i+1)$  and, if  $T(i:i+1,i:i+1)$  is a 2-by-2 diagonal block,  $\text{wi}[i-1] > 0$  and  $\text{wi}[i] = -\text{wi}[i-1]$ .

Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

$m$

(global )

The size of the specified invariant subspace.  $0 \leq m \leq n$ .

$s$

(global )

If  $\text{job} = \text{'E'}$  or  $\text{'B'}$ ,  $s$  is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues.  $s$  cannot underestimate the true reciprocal condition number by more than a factor of  $\sqrt{n}$ . If  $m = 0$  or  $n$ ,  $s = 1$ .

If  $\text{job} = \text{'N'}$  or  $\text{'V'}$ ,  $s$  is not referenced.

$\text{sep}$

(global )

If  $\text{job} = \text{'V'}$  or  $\text{'B'}$ ,  $\text{sep}$  is the estimated reciprocal condition number of the specified invariant subspace. If

$m = 0$  or  $n$ ,  $\text{sep} = \text{norm}(t)$ .

If  $\text{job} = \text{'N'}$  or  $\text{'E'}$ ,  $\text{sep}$  is not referenced.

$\text{work}[0]$

On exit, if  $\text{info} = 0$ ,  $\text{work}[0]$  returns the optimal  $\text{lwork}$ .

$\text{iwork}[0]$

On exit, if  $\text{info} = 0$ ,  $\text{iwork}[0]$  returns the optimal  $\text{liwork}$ .

$\text{info}$

(global )

= 0: successful exit

< 0: if  $\text{info} = -i$ , the  $i$ -th argument had an illegal value.

If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $\text{info} = -(i*1000+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $\text{info} = -i$ .

> 0: here we have several possibilities

- Reordering of  $t$  failed because some eigenvalues are too close to separate (the problem is very ill-conditioned);  $t$  may have been partially reordered, and  $\text{wr}$  and  $\text{wi}$  contain the eigenvalues in the same order as in  $t$ .

On exit,  $\text{info} = \{\text{the index of } t \text{ where the swap failed (indexing starts at 1)}\}$ .

- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

On exit,  $\text{info} = \{\text{the index of } t \text{ where the swap failed}\}$ .

- If  $\text{info} = n+1$ , there is no valid BLACS context (see the BLACS documentation for details).

## Application Notes

The following alignment requirements must hold:

- $mb_t = nb_t = mb_q = nb_q$
- $rsrc_t = rsrc_q$
- $csrc_t = csrc_q$

All matrices must be blocked by a block factor larger than or equal to two (3). This to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of  $t$  and  $q$ , i.e.,  $it = jt = iq = jq = 1$  must hold. This is however no limitation since [p?lahqr](#) does not compute Schur forms of submatrices anyway.

For parallel execution, use a square grid, if possible, for maximum performance. The block parameters in *para* should be kept well below the data distribution block size.

In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

## p?trti2

*Computes the inverse of a triangular matrix (local unblocked algorithm).*

---

## Syntax

```
void pstrti2 (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info);
void pdtrti2 (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info);
void pctrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info);
void pztrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?trti2` function computes the inverse of a real/complex upper or lower triangular block matrix sub ( $A$ )  
=  $A(ia:ia+n-1, ja:ja+n-1)$ .

This matrix should be contained in one and only one process memory space (local operation).

## Input Parameters

|             |                                                                        |
|-------------|------------------------------------------------------------------------|
| <i>uplo</i> | (global)                                                               |
|             | Specifies whether the matrix sub ( $A$ ) is upper or lower triangular. |
|             | = 'U': sub ( $A$ ) is upper triangular                                 |
|             | = 'L': sub ( $A$ ) is lower triangular.                                |
| <i>diag</i> | (global)                                                               |

Specifies whether or not the matrix  $A$  is unit triangular.

= 'N': sub ( $A$ ) is non-unit triangular

= 'U': sub ( $A$ ) is unit triangular.

$n$

(global)  
The number of rows and columns to be operated on, i.e., the order of the distributed submatrix sub ( $A$ ).  $n \geq 0$ .

$a$

(local)

Pointer into the local memory to an array, size  $l1d\_a * LOCc(ja+n-1)$ .

On entry, this array contains the local pieces of the triangular matrix sub( $A$ ).

If  $uplo = 'U'$ , the leading  $n$ -by- $n$  upper triangular part of the matrix sub( $A$ ) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub( $A$ ) is not referenced.

If  $uplo = 'L'$ , the leading  $n$ -by- $n$  lower triangular part of the matrix sub( $A$ ) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub( $A$ ) is not referenced. If  $diag = 'U'$ , the diagonal elements of sub( $A$ ) are not referenced either and are assumed to be 1.

$ia, ja$

(global)  
The row and column indices in the global matrix  $A$  indicating the first row and the first column of the sub( $A$ ), respectively.

$desca$

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

## Output Parameters

$a$

On exit, the (triangular) inverse of the original matrix, in the same storage format.

$info$

= 0: successful exit

< 0: if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value,

then  $info = -(i*100+j)$ ,

if the  $i$ -th argument is a scalar and had an illegal value,

then  $info = -i$ .

## ?lahqr2

[Updates the eigenvalues and Schur decomposition.](#)

## Syntax

```
void clahqr2 (const MKL_INT* wantt, const MKL_INT* wantz, const MKL_INT* n, const
MKL_INT* ilo, const MKL_INT* ihi, MKL_Complex8* h, const MKL_INT* ldh, MKL_Complex8* w,
const MKL_INT* iloz, const MKL_INT* ihiz, MKL_Complex8* z, const MKL_INT* ldz, MKL_INT*
info);

void zlahqr2 (const MKL_INT* wantt, const MKL_INT* wantz, const MKL_INT* n, const
MKL_INT* ilo, const MKL_INT* ihi, MKL_Complex16* h, const MKL_INT* ldh, MKL_Complex16*
w, const MKL_INT* iloz, const MKL_INT* ihiz, MKL_Complex16* z, const MKL_INT* ldz,
MKL_INT* info);
```

## Include Files

- mkl\_scalapack.h

## Description

?lahqr2 is an auxiliary routine called by ?hseqr to update the eigenvalues and Schur decomposition already computed by ?hseqr, by dealing with the Hessenberg submatrix in rows and columns *ilo* to *ihi*. This version of ?lahqr (not the standard LAPACK version) uses a double-shift algorithm (like LAPACK's ?lahqr). Unlike the standard LAPACK convention, this does not assume the subdiagonal is real, nor does it work to preserve this quality if given.

## Input Parameters

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>wantt</i>      | # 0: the full Schur form <i>T</i> is required;<br>= 0: only eigenvalues are required.                                                                                                                                                                                                                                                                                                                                                 |

| <i>iloz, ihiz</i> | Specify the rows of <i>Z</i> to which transformations must be applied if <i>wantz</i> ≠ 0.<br><br><i>1 &lt;= iloz &lt;= ilo; ihi &lt;= ihiz &lt;= n.</i>                                                                                                                                                                                                                                                                              |
| <i>z</i>          | Array, size <i>ldz</i> * <i>n</i> .<br><br>If <i>wantz</i> ≠ 0, on entry <i>z</i> must contain the current matrix <i>Z</i> of transformations. If <i>wantz</i> = 0, <i>z</i> is not referenced.                                                                                                                                                                                                                                       |

*ldz*The leading dimension of the array *z*.  $ldz \geq \max(1, n)$ .

## Output Parameters

*h*On exit, if  $wantt \neq 0$ , *h* is upper triangular in rows and columns *ilo:ih*. If  $wantt = 0$ , the contents of *h* are unspecified on exit.*w*Array, size (*n*)The computed eigenvalues *ilo* to *ih* are stored in the corresponding elements of *w*. If  $wantt \neq 0$ , the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with  $w[i] = H(i, i)$ .*z*If  $wantz \neq 0$ , on exit *z* has been updated; transformations are applied only to the submatrix  $Z(iloz:ihiz, ilo:ih)$ . If  $wantz = 0$ , *z* is not referenced.*info*

= 0: successful exit

> 0: if *info* = *i*, ?lahqr failed to compute all the eigenvalues *ilo* to *ih* in a total of  $30*(ih-i+1)$  iterations; elements *w[i:ih - 1]* contain those eigenvalues which have been successfully computed.

## ?lamsh

*Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.*

## Syntax

```
void slamsh (float *s, const MKL_INT *lds, MKL_INT *nbudge, const MKL_INT *jblk, float *h, const MKL_INT *ldh, const MKL_INT *n, const float *ulp);
void dlamsh (double *s, const MKL_INT *lds, MKL_INT *nbudge, const MKL_INT *jblk,
double *h, const MKL_INT *ldh, const MKL_INT *n, const double *ulp);
void clamsh (MKL_Complex8 *s , const MKL_INT *lds , MKL_INT *nbudge , const MKL_INT *jblk ,
MKL_Complex8 *h , const MKL_INT *ldh , const MKL_INT *n , const float *ulp);
void zlamsh (MKL_Complex16 *s , const MKL_INT *lds , MKL_INT *nbudge , const MKL_INT *jblk ,
MKL_Complex16 *h , const MKL_INT *ldh , const MKL_INT *n , const double *ulp);
```

## Include Files

- mkl\_scalapack.h

## Description

The ?lamshfunction sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The function should only be called when there are multiple shifts/bulges ( $nbudge > 1$ ) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

## Input Parameters

|               |                                                                                                                                                                                                                  |

## ?lapst

Sorts the numbers in increasing or decreasing order.

## Syntax

```
void slapst (const char* id, const MKL_INT* n, const float* d, MKL_INT* indx, MKL_INT* info);
```

---

```
void dlapst (const char* id, const MKL_INT* n, const double* d, MKL_INT* indx, MKL_INT* info);
```

## Include Files

- mkl\_scalapack.h

## Description

?lapst is a modified version of the LAPACK routine ?lasrt.

Define a permutation *indx* that sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D' ).

Use Quick Sort, reverting to Insertion sort on arrays of size <= 20. Dimension of STACK limits *n* to about  $2^{32}$ .

## Input Parameters

|           |                                                                                        |
|-----------|----------------------------------------------------------------------------------------|
| <i>id</i> | = 'I': sort <i>d</i> in increasing order;<br>= 'D': sort <i>d</i> in decreasing order. |
| <i>n</i>  | The length of the array <i>d</i> .                                                     |

## Description

This auxiliary function performs a single small-bulge multi-shift QR sweep, moving the chain of bulges from top to bottom in the submatrix  $H(k_{top}:k_{bot}, k_{top}:k_{bot})$ , collecting the transformations in the matrix  $V$  or accumulating the transformations in the matrix  $Z$  (see below).

This is a modified version of `?laqr5` from LAPACK 3.1.

## Input Parameters

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>job</i>                | Set the kind of job to do in <code>?laqr6</code> , as follows:<br><br><code>job = 'I'</code> : Introduce and chase bulges in submatrix<br><code>job = 'C'</code> : Chase bulges from top to bottom of submatrix<br><code>job = 'O'</code> : Chase bulges off submatrix                                                                                                                                                                                                                                                                                                   |
| <i>wantt</i>              | <i>wantt</i> is non-zero if the quasi-triangular Schur factor is being computed.<br><i>wantt</i> is set to zero otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Description

?slar1va computes the (scaled)  $r$ -th column of the inverse of the submatrix in rows  $b1$  through  $bn$  of the tridiagonal matrix  $LDL^T - \lambda I$ . When  $\lambda$  is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually,  $r$  corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation :

1. Stationary qd transform,  $LDL^T - \lambda I = L_+ D_+ L_+^T$ ,
2. Progressive qd transform,  $LDL^T - \lambda I = U D_- U_-^T$ ,
3. Computation of the diagonal elements of the inverse of  $LDL^T - \lambda I$  by combining the above transforms, and choosing  $r$  as the index where the diagonal of the inverse is (one of the) largest in magnitude.
4. Computation of the (scaled)  $r$ -th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

## Input Parameters

|          |                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------|
| $n$      | The order of the matrix $LDL^T$ .                                                                                                        |
| $b1$     | First index of the submatrix of $LDL^T$ .                                                                                                |
| $bn$     | Last index of the submatrix of $LDL^T$ .                                                                                                 |
| $lambda$ | The shift $\lambda$ . In order to compute an accurate eigenvector, $lambda$ should be a good approximation to an eigenvalue of $LDL^T$ . |
| $l$      | Array of size $n-1$                                                                                                                      |
|          | The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix $L$ , in elements 0 to $n-2$ .                                            |
| $d$      | Array of size $n$                                                                                                                        |
|          | The $n$ diagonal elements of the diagonal matrix $D$ .                                                                                   |
| $ld$     | Array of size $n-1$                                                                                                                      |
|          | The $n-1$ elements $l[i]*d[i]$ , $i=0,\dots,n-2$ .                                                                                       |

---

|               |                                                                                                                                                                                                                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>lld</i>    | Array of size $n-1$                                                                                                                                                                                                                                                                                                                                            |
|               | The $n-1$ elements $\lambda[i]*\lambda[j]*d[i]$ , $i=0,\dots,n-2$ .                                                                                                                                                                                                                                                                                            |
| <i>pivmin</i> | The minimum pivot in the Sturm sequence.                                                                                                                                                                                                                                                                                                                       |
| <i>gaptol</i> | Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.                                                                                                                                                                                                                                           |
| <i>z</i>      | Array of size $n$                                                                                                                                                                                                                                                                                                                                              |
|               | On input, all entries of <i>z</i> must be set to 0.                                                                                                                                                                                                                                                                                                            |
| <i>wantnc</i> | Specifies whether <i>negcnt</i> has to be computed.                                                                                                                                                                                                                                                                                                            |
| <i>r</i>      | The twist index for the twisted factorization used to compute <i>z</i> .<br>On input, $0 \leq r \leq n$ . If <i>r</i> is input as 0, <i>r</i> is set to the index where $(LDL^T - \sigma I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$ , <i>r</i> is unchanged.<br>Ideally, <i>r</i> designates the position of the maximum entry in the eigenvector. |
| <i>work</i>   | (Workspace) array of size $4*n$                                                                                                                                                                                                                                                                                                                                |

## OUTPUT Parameters

|               |                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>z</i>      | On output, <i>z</i> contains the (scaled) <i>r</i> -th column of the inverse. The scaling is such that $z[r-1]$ equals 1.                                 |
| <i>negcnt</i> | If <i>wantnc</i> is non-zero then <i>negcnt</i> = the number of pivots $< pivmin$ in the matrix factorization $LDL^T$ , and <i>negcnt</i> = -1 otherwise. |
| <i>ztz</i>    | The square of the 2-norm of <i>z</i> .                                                                                                                    |
| <i>mingma</i> | The reciprocal of the largest (in magnitude) diagonal element of the inverse of $LDL^T - \sigma I$ .                                                      |
| <i>r</i>      | On output, <i>r</i> contains the twist index used to compute <i>z</i> .                                                                                   |
| <i>isuppz</i> | array of size 2<br>The support of the vector in <i>z</i> , i.e., the vector <i>z</i> is non-zero only in elements <i>isuppz[0]</i> and <i>isuppz[1]</i> . |
| <i>nrminv</i> | $nrminv = 1/\text{SQRT}( ztz )$                                                                                                                           |
| <i>resid</i>  | The residual of the FP vector.<br>$resid = \text{ABS}( mingma )/\text{SQRT}( ztz )$                                                                       |
| <i>rqcorr</i> | The Rayleigh Quotient correction to <i>lambda</i> .                                                                                                       |

## Description

?laref applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

## Input Parameters

|              |                                                                      |
|--------------|----------------------------------------------------------------------|
| <i>type</i>  | (local)                                                              |
|              | If 'R': Apply reflectors to the rows of the matrix (apply from left) |
|              | Otherwise: Apply reflectors to the columns of the matrix             |
|              | Unchanged on exit.                                                   |
| <i>a</i>     | (local)                                                              |
|              | Array, $\ d_a^*LOCc(ja+n-1)$                                         |
|              | On entry, the matrix to receive the reflections.                     |
| <i>lda</i>   | (local)                                                              |
|              | On entry, the leading dimension of <i>a</i> .                        |
|              | Unchanged on exit.                                                   |
| <i>wantz</i> | (local)                                                              |

If  $wantz \neq 0$ , then apply any column reflections to  $z$  as well.

If  $wantz = 0$ , then do no additional work on  $z$ .

$z$

(local)

Array,  $ldz * ncols$ , where the value  $ncols$  depends on other arguments. If  $wantz \neq 0$  and  $type \neq 'R'$  then  $ncols = icoll + 3*(lihiz - lilo_z + 1)$ . Otherwise,  $ncols$  is unused.

On entry, the second matrix to receive column reflections.

This is changed only if  $wantz$  is set.

$ldz$

(local)

On entry, the leading dimension of  $z$ .

Unchanged on exit.

$block$

(local)

If nonzero, then apply several reflectors at once and read their data from the  $vecs$  array.

If zero, apply the single reflector given by  $v2$ ,  $v3$ ,  $t1$ ,  $t2$ , and  $t3$ .

$irow1$

(local)

On entry, the local row element of  $a$ .

$icoll$

(local)

On entry, the local column element of  $a$ .

$istart$

(local)

Specifies the "number" of the first reflector. This is used as an index into  $vecs$  if  $block$  is set.  $istart$  is ignored if  $block$  is zero.

$istop$

(local)

Specifies the "number" of the last reflector. This is used as an index into  $vecs$  if  $block$  is set.  $istop$  is ignored if  $block$  is zero.

$itmp1$

(local)

Starting range into  $a$ . For rows, this is the local first column. For columns, this is the local first row.

$itmp2$

(local)

Ending range into  $a$ . For rows, this is the local last column. For columns, this is the local last row.

$lilo_z, lihiz$

(local)

These serve the same purpose as  $itmp1$ ,  $itmp2$  but for  $z$  when  $wantz$  is set.

$vecs$

(local)

Array of size  $3 \times N$  (matrix size)

This holds the size 3 reflectors one after another and this is only accessed when *block* is nonzero

*v2, v3, t1, t2, t3*

(local)

This holds information on a single size 3 Householder reflector and is read when *block* is zero, and overwritten when *block* is nonzero

## Output Parameters

|                           |                                              |
|---------------------------|----------------------------------------------|
| <i>a</i>                  | The updated matrix on exit.                  |
| <i>z</i>                  | This is changed only if <i>wantz</i> is set. |
| <i>irow1</i>              | Undefined on output.                         |
| <i>icoll</i>              | Undefined on output.                         |
| <i>v2, v3, t1, t2, t3</i> | Overwritten when <i>block</i> is nonzero.    |

## ?larrb2

Provides limited bisection to locate eigenvalues for more accuracy.

---

## Syntax

```
void slarrb2(MKL_INT* n, float* d, float* lld, MKL_INT* ifirst, MKL_INT* ilast, float* rtol1, float* rtol2, MKL_INT* offset, float* w, float* wgap, float* werr, float* work, MKL_INT* iwork, float* pivmin, float* lgpvmn, float* lgspdm, MKL_INT* twist, MKL_INT* info);

void dlarrb2(MKL_INT* n, double* d, double* lld, MKL_INT* ifirst, MKL_INT* ilast, double* rtol1, double* rtol2, MKL_INT* offset, double* w, double* wgap, double* werr, double* work, MKL_INT* iwork, double* pivmin, double* lgpvmn, double* lgspdm, MKL_INT* twist, MKL_INT* info);
```

## Include Files

- mkl\_scalapack.h

## Description

Given the relatively robust representation (RRR)  $LDL^T$ , ?larrb2 does "limited" bisection to refine the eigenvalues of  $LDL^T$  with indices in a given range to more accuracy. Initial guesses for these eigenvalues are input in *w*, the corresponding estimate of the error in these guesses and their gaps are input in *werr* and *wgap*, respectively. During bisection, intervals  $[left, right]$  are maintained by storing their mid-points and semi-widths in the arrays *w* and *werr* respectively. The range of indices is specified by the *ifirst*, *ilast*, and *offset* parameters, as explained in [Input Parameters](#).

**NOTE**

There are very few minor differences between `larrb` from LAPACK and this current function `?larrb2`. The most important reason for creating this nearly identical copy is profiling: in the ScaLAPACK MRRR algorithm, eigenvalue computation using `?larrb2` is used for refinement in the construction of the representation tree, as opposed to the initial computation of the eigenvalues for the root RRR which uses `?larrb`. When profiling, this allows an easy quantification of refinement work vs. computing eigenvalues of the root.

**Input Parameters**

|                           |                                                                                                                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>            | The order of the matrix.                                                                                                                                                                                                                                                                     |
| <code>d</code>            | Array of size $n$ .<br>The $n$ diagonal elements of the diagonal matrix $D$ .                                                                                                                                                                                                                |
| <code>lld</code>          | Array of size $n-1$ .<br>The $(n-1)$ elements $l_{i+1} * l_{i+1}^* d[i]$ , $i=0, \dots, n-2$ .                                                                                                                                                                                               |
| <code>ifirst</code>       | The index of the first eigenvalue to be computed.                                                                                                                                                                                                                                            |
| <code>ilast</code>        | The index of the last eigenvalue to be computed.                                                                                                                                                                                                                                             |
| <code>rto11, rto12</code> | Tolerance for the convergence of the bisection intervals.<br>An interval $[left, right]$ has converged if $right - left < \max(rto11 * gap, rto12 * \max( left ,  right ))$ where $gap$ is the (estimated) distance to the nearest eigenvalue.                                               |
| <code>offset</code>       | Offset for the arrays <code>w</code> , <code>wgap</code> and <code>werr</code> , i.e., the elements indexed <code>ifirst - offset</code> through <code>ilast - offset</code> of these arrays are to be used.                                                                                 |
| <code>w</code>            | Array of size $n$<br>On input, $w[ifirst - offset - 1]$ through $w[ilast - offset - 1]$ are estimates of the eigenvalues of $LDL^T$ indexed <code>ifirst</code> through <code>ilast</code> .                                                                                                 |
| <code>wgap</code>         | Array of size $n-1$ .<br>On input, the (estimated) gaps between consecutive eigenvalues of $LDL^T$ , i.e., $wgap[I - offset - 1]$ is the gap between eigenvalues $I$ and $I + 1$ . Note that if <code>ifirst = ilast</code> then <code>wgap[ifirst - offset - 1]</code> must be set to zero. |
| <code>werr</code>         | Array of size $n$ .<br>On input, $werr[ifirst - offset - 1]$ through $werr[ilast - offset - 1]$ are the errors in the estimates of the corresponding elements in <code>w</code> .                                                                                                            |
| <code>work</code>         | (workspace) array of size $4*n$ .<br>Workspace.                                                                                                                                                                                                                                              |
| <code>iwork</code>        | (workspace) array of size $2*n$ .<br>Workspace.                                                                                                                                                                                                                                              |
| <code>pivmin</code>       | The minimum pivot in the Sturm sequence.                                                                                                                                                                                                                                                     |

|               |                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>lgpvmn</i> | Logarithm of <i>pivmin</i> , precomputed.                                                                                                                                                                                                                                                                                                                                |
| <i>lgspdm</i> | Logarithm of the spectral diameter, precomputed.                                                                                                                                                                                                                                                                                                                         |
| <i>twist</i>  | The twist index for the twisted factorization that is used for the <i>negcount</i> .<br><i>twist = n</i> : Compute <i>negcount</i> from $LDL^T - \lambda I = L_+D_+L_+^T$<br><i>twist = 1</i> : Compute <i>negcount</i> from $LDL^T - \lambda I = U_-D_-U_-^T$<br><i>twist = r</i> , $1 < r < n$ : Compute <i>negcount</i> from $LDL^T - \lambda I = N_r \Delta_r N_r^T$ |

## OUTPUT Parameters

## Description

?larrd2 computes the eigenvalues of a symmetric tridiagonal matrix  $T$  to limited initial accuracy. This is an auxiliary code to be called from [larr2a](#).

?larrd2 has been created using the LAPACK code `larrd` which itself stems from [stebz](#). The motivation for creating ?larrd2 is efficiency: When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, ?larrd2 can skip over blocks which contain none of the eigenvalues from DOL to DOU for which the processor responsible. In extreme cases (such as large matrices consisting of many blocks of small size like 2x2), the gain can be substantial.

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

## Input Parameters

|                       |                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>range</i>          | = 'A': ("All") all eigenvalues will be found.<br>= 'V': ("Value") all eigenvalues in the half-open interval ( <i>vl</i> , <i>vu</i> ] will be found.<br>= 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.                                                                                                   |
| <i>order</i>          | = 'B': ("By Block") the eigenvalues will be grouped by split-off block (see <i>iblock</i> , <i>isplit</i> ) and ordered from smallest to largest within the block.<br>= 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.                                                                               |
| <i>n</i>              | The order of the tridiagonal matrix <i>T</i> . <i>n</i> >= 0.                                                                                                                                                                                                                                                                                                |
| <i>vl</i> , <i>vu</i> | If <i>range</i> ='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to <i>vl</i> , or greater than <i>vu</i> , will not be returned. <i>vl</i> < <i>vu</i> .<br><br>Not referenced if <i>range</i> = 'A' or 'I'.                                                                                 |
| <i>il</i> , <i>iu</i> | If <i>range</i> ='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in <i>w</i> [ <i>il</i> -1], and largest eigenvalue, to be returned in <i>w</i> [ <i>iu</i> -1].<br><br>$1 \leq il \leq iu \leq n$ , if <i>n</i> > 0; <i>il</i> = 1 and <i>iu</i> = 0 if <i>n</i> = 0.<br><br>Not referenced if <i>range</i> = 'A' or 'V'. |
| <i>gers</i>           | Array of size $2*n$<br><br>The <i>n</i> Gerschgorin intervals (the <i>i</i> -th Gerschgorin interval is ( <i>gers</i> [ $2*i-2$ ], <i>gers</i> [ $2*i-1$ ])).                                                                                                                                                                                                |
| <i>reltol</i>         | The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.                                                                                            |
| <i>d</i>              | Array of size <i>n</i><br><br>The <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> .                                                                                                                                                                                                                                                            |
| <i>e</i>              | Array of size <i>n</i> -1<br><br>The ( <i>n</i> -1) off-diagonal elements of the tridiagonal matrix <i>T</i> .                                                                                                                                                                                                                                               |
| <i>e2</i>             | Array of size <i>n</i> -1<br><br>The ( <i>n</i> -1) squared off-diagonal elements of the tridiagonal matrix <i>T</i> .                                                                                                                                                                                                                                       |
| <i>pivmin</i>         | The minimum pivot allowed in the sturm sequence for <i>T</i> .                                                                                                                                                                                                                                                                                               |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>nsplit</i>   | The number of diagonal blocks in the matrix $T$ .<br>$1 \leq nsplit \leq n$ .                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>isplit</i>   | Array of size $n$<br>The splitting points, at which $T$ breaks up into submatrices.<br>The first submatrix consists of rows/columns 1 to $isplit[0]$ , the second of rows/columns $isplit[0]+1$ through $isplit[1]$ , etc., and the $nsplit$ -th submatrix consists of rows/columns $isplit[nsplit-2]+1$ through $isplit[nsplit-1]=n$ .<br>(Only the first $nsplit$ elements will actually be used, but since the user cannot know a priori what value $nsplit$ will have, $n$ words must be reserved for <i>isplit</i> .) |
| <i>work</i>     | (workspace) Array of size $4*n$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>iwork</i>    | (workspace) Array of size $3*n$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>dol, dou</i> | Specifying an index range $dol:dou$ allows the user to work on only a selected part of the representation tree.<br>Otherwise, the setting $dol=1, dou=n$ should be applied.<br>Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>W</i> .                                                                                                                                                                                                                                    |

## OUTPUT Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>      | The actual number of eigenvalues found. $0 \leq m \leq n$ .<br>(See also the description of <i>info</i> =2,3.)                                                                                                                                                                                                                                                                |
| <i>w</i>      | Array of size $n$<br>On exit, the first <i>m</i> elements of <i>w</i> will contain the eigenvalue approximations. ?larrd2 computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue <i>j</i> . The eigenvalue approximation is given as the interval midpoint $w[j-1] = (a_j + b_j)/2$ . The corresponding error is bounded by $werr[j-1] = \text{abs}(a_j - b_j)/2$ . |
| <i>werr</i>   | Array of size $n$<br>The error bound on the corresponding eigenvalue approximation in <i>w</i> .                                                                                                                                                                                                                                                                              |
| <i>wl, wu</i> | The interval ( <i>wl, wu</i> ) contains all the wanted eigenvalues.<br>If <i>range</i> ='V', then <i>wl</i> = <i>vl</i> and <i>wu</i> = <i>vu</i> .<br>If <i>range</i> ='A', then <i>wl</i> and <i>wu</i> are the global Gershgorin bounds on the spectrum.<br>If <i>range</i> ='I', then <i>wl</i> and <i>wu</i> are computed by SLAEBZ from the index range specified.      |
| <i>iblock</i> | Array of size $n$                                                                                                                                                                                                                                                                                                                                                             |

At each row/column  $j$  where  $e[j-1]$  is zero or small, the matrix  $T$  is considered to split into a block diagonal matrix. On exit, if  $info = 0$ ,  $iblock[i]$  specifies to which block (from 0 to the number of blocks minus one) the eigenvalue  $w[i]$  belongs. (?larrd2 may use the remaining  $n-m$  elements as workspace.)

*indexw*

Array of size  $n$

The indices of the eigenvalues within each block (submatrix); for example,  $indexw[i]=j$  and  $iblock[i]=k$  imply that the  $(i+1)$ -th eigenvalue  $w[i]$  is the  $j$ -th eigenvalue in block  $k$ .

*info*

= 0: successful exit

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value

> 0: some or all of the eigenvalues failed to converge or were not computed:

- =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.
- =2 or 3:  $range='I'$  only: Not all of the eigenvalues  $il:iu$  were found.
- = 4:  $range='I'$ , and the Gershgorin interval initially used was too small. No eigenvalues were computed.

## Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix  $T$ , ?larre2 sets, via ?larra, "small" off-diagonal elements to zero. For each block  $T_i$ , it finds

- a suitable shift at one end of the block's spectrum,

- the root RRR,  $T_i - \sigma_i I = L_i D_i L_i^T$ , and
- eigenvalues of each  $L_i D_i L_i^T$ .

The representations and eigenvalues found are then returned to `?steqr2` to compute the eigenvectors  $T$ .

`?larre2` is more suitable for parallel computation than the original LAPACK code for computing the root RRR and its eigenvalues. When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, `?larre2` can skip over blocks which contain none of the eigenvalues from `d01` to `d04` for which the processor is responsible. In extreme cases (such as large matrices consisting of many blocks of small size, e.g. 2x2), the gain can be substantial.

*dol, dou* Specifying an index range  $dol:dou$  allows the user to work on only a selected part of the representation tree. Otherwise, the setting  $dol=1$ ,  $dou=n$  should be applied.

Note that  $dol$  and  $dou$  refer to the order in which the eigenvalues are stored in  $w$ .

*work* Workspace array of size  $6*n$

*iwork* Workspace array of size  $5*n$

## OUTPUT Parameters

*vl, vu* If  $range='I'$  or  $'A'$ , ?larre2 contains bounds on the desired part of the spectrum.

*d* The  $n$  diagonal elements of the diagonal matrices  $D_i$ .

*e*  $e$  contains the subdiagonal elements of the unit bidiagonal matrices  $L_i$ . The entries  $e[isplit[i]], 0 \leq i < nsplit$ , contain the base points  $\sigma_{i+1}$  on output.

*e2* The entries  $e2[isplit[i]], 0 \leq i < nsplit$ , are set to zero.

*nsplit* The number of blocks  $T$  splits into.  $1 \leq nsplit \leq n$ .

*isplit* Array of size  $n$

The splitting points, at which  $T$  breaks up into blocks.

The first block consists of rows/columns 1 to  $isplit[0]$ , the second of rows/columns  $isplit[0]+1$  through  $isplit[1]$ , etc., and the  $nsplit$ -th block consists of rows/columns  $isplit[nsplit-2]+1$  through  $isplit[nsplit-1]=n$ .

*m* The total number of eigenvalues (of all  $L_i D_i L_i^T$ ) found.

*w* Array of size  $n$

The first  $m$  elements contain the eigenvalues. The eigenvalues of each of the blocks,  $L_i D_i L_i^T$ , are sorted in ascending order (?larre2 may use the remaining  $n-m$  elements as workspace).

Note that immediately after exiting this function, only the eigenvalues in  $w$  with indices in range  $dol-1:dou-1$  might rely on this processor when the eigenvalue computation is done in parallel.

*werr* Array of size  $n$

The error bound on the corresponding eigenvalue in  $w$ .

Note that immediately after exiting this function, only the uncertainties in  $werr$  with indices in range  $dol-1:dou-1$  might rely on this processor when the eigenvalue computation is done in parallel.

*wgap* Array of size  $n$

The separation from the right neighbor eigenvalue in  $w$ .

The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.

Exception: at the right end of a block we store the left gap

Note that immediately after exiting this function, only the gaps in  $wgap$  with indices in range  $dol-1:dou-1$  might rely on this processor when the eigenvalue computation is done in parallel.

*iblock*

Array of size  $n$

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in  $w$ ;  $iblock[i]=1$  if eigenvalue  $w[i]$  belongs to the first block from the top,  $iblock[i]=2$  if  $w[i]$  belongs to the second block, and so on.

*indexw*

Array of size  $n$

The indices of the eigenvalues within each block (submatrix); for example,  $indexw[i]=10$  and  $iblock[i]=2$  imply that the  $(i+1)$ -th eigenvalue  $w[i]$  is the 10th eigenvalue in block 2.

*gers*

Array of size  $2*n$

The  $n$  Gerschgorin intervals (the  $i$ -th Gerschgorin interval is  $(gers[2*i-2], gers[2*i-1])$ ).

*pivmin*

The minimum pivot in the sturm sequence for  $T$ .

*info*

= 0: successful exit

> 0: A problem occurred in `?larre2`.

< 0: One of the called functions signaled an internal problem.

Needs inspection of the corresponding parameter *info* for further information.

=-1: Problem in `?larrd`.

=-2: Not enough internal iterations to find the base representation.

=-3: Problem in `?larrb` when computing the refined root representation for `?lasq2`.

=-4: Problem in `?larrb` when performing bisection on the desired part of the spectrum.

=-5: Problem in `?lasq2`

=-6: Problem in `?lasq2`

## Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix  $T$ , `?larre2a` sets any "small" off-diagonal elements to zero, and for each unreduced block  $T_i$ , it finds

- a suitable shift at one end of the block's spectrum,
- the base representation,  $T_i - \sigma_i I = L_i D_i L_i^T$ , and
- eigenvalues of each  $L_i D_i L_i^T$ .

---

### NOTE

The algorithm obtains a crude picture of all the wanted eigenvalues (as selected by `range`). However, to reduce work and improve scalability, only the eigenvalues `dol` to `dou` are refined. Furthermore, if the matrix splits into blocks, RRRs for blocks that do not contain eigenvalues from `dol` to `dou` are skipped. The DQDS algorithm (function `?lasq2`) is not used, unlike in the sequential case. Instead, eigenvalues are computed in parallel to some figures using bisection.

| <i>work</i>         | Workspace array of size $6 * n$                                                                                                                                                                                                                                                                           |
| <i>iwork</i>        | Workspace array of size $5 * n$                                                                                                                                                                                                                                                                           |
| <i>minrgp</i>       | The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.                                                                                                                                                                                                      |

## OUTPUT Parameters

|               |                                                                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vl, vu</i> | If <i>range</i> ='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i> , or greater than <i>vu</i> , are not returned. <i>vl &lt; vu</i> .<br>If <i>range</i> ='I' or <i>range</i> ='A', ?larre2a computes bounds on the desired part of the spectrum. |
| <i>d</i>      | The <i>n</i> diagonal elements of the diagonal matrices <i>D<sub>i</sub></i> .                                                                                                                                                                                                                    |
| <i>e</i>      | <i>e</i> contains the subdiagonal elements of the unit bidiagonal matrices <i>L<sub>i</sub></i> . The entries <i>e[isplit[i]]</i> , $0 \leq i \leq n_{split}$ , contain the base points $\sigma_{i+1}$ on output.                                                                                 |
| <i>e2</i>     | The entries <i>e2[isplit[i]]</i> , $0 \leq i \leq n_{split}$ have been set to zero.                                                                                                                                                                                                               |
| <i>nsplit</i> | The number of blocks <i>T</i> splits into. $1 \leq n_{split} \leq n$ .                                                                                                                                                                                                                            |
| <i>isplit</i> | Array of size <i>n</i><br>The splitting points, at which <i>T</i> breaks up into blocks.                                                                                                                                                                                                          |

The first block consists of rows/columns 1 to  $isplit[0]$ , the second of rows/columns  $isplit[0]+1$  through  $isplit[1]$ , etc., and the  $nsplit$ -th block consists of rows/columns  $isplit[nsplit-2]+1$  through  $isplit[nsplit-1]=n$ .

*m*

The total number of eigenvalues (of all  $L_i D_i L_i^T$ ) found.

*needil, neediu*

The indices of the leftmost and rightmost eigenvalues of the root node RRR which are needed to accurately compute the relevant part of the representation tree.

*w*

Array of size *n*

The first *m* elements contain the eigenvalues. The eigenvalues of each of the blocks,  $L_i D_i L_i^T$ , are sorted in ascending order (`?larre2a` may use the remaining *n-m* elements as workspace).

Note that immediately after exiting this function, only the eigenvalues in *w* with indices in range  $dol-1:dou-1$  rely on this processor because the eigenvalue computation is done in parallel.

*werr*

Array of size *n*

The error bound on the corresponding eigenvalue in *w*.

Note that immediately after exiting this function, only the uncertainties in *werr* with indices in range  $dol-1:dou-1$  are reliable on this processor because the eigenvalue computation is done in parallel.

*wgap*

Array of size *n*

The separation from the right neighbor eigenvalue in *w*. The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.

Exception: at the right end of a block we store the left gap

Note that immediately after exiting this function, only the gaps in *wgap* with indices in range  $dol-1:dou-1$  are reliable on this processor because the eigenvalue computation is done in parallel.

*iblock*

Array of size *n*

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in *w*;  $iblock[i]=1$  if eigenvalue *w*[*i*] belongs to the first block from the top,  $iblock[i]=2$  if *w*[*i*] belongs to the second block, and so on.

*indexw*

Array of size *n*

The indices of the eigenvalues within each block (submatrix); for example,  $indexw[i]=10$  and  $iblock[i]=2$  imply that the (*i*+1)-th eigenvalue *w*[*i*] is the 10th eigenvalue in block 2.

*gers*

Array of size  $2*n$

The *n* Gerschgorin intervals (the *i*-th Gerschgorin interval is ( $gers[2*i-2]$ ,  $gers[2*i-1]$ )).

*pivmin*

The minimum pivot in the sturm sequence for *T*.

*info*

= 0: successful exit

> 0: A problem occurred in ?larre2a.

< 0: One of the called functions signaled an internal problem. Needs inspection of the corresponding parameter *info* for further information.

=-1: Problem in ?larrd2.

=-2: Not enough internal iterations to find base representation.

=-3: Problem in ?larrb2 when computing the refined root representation.

=-4: Problem in ?larrb2 when performing bisection on the desired part of the spectrum.

= -9 Problem:  $m < \text{dou-dol}+1$ , that is the code found fewer eigenvalues than it was supposed to.

## Description

Given the initial representation  $LDL^T$  and its cluster of close eigenvalues (in a relative measure), defined by the indices of the first and last eigenvalues in the cluster, ?larrf2 finds a new relatively robust representation  $LDL^T - \sigma I = L_+D_+L_+^T$  such that at least one of the eigenvalues of  $L_+D_+L_+^T$  is relatively isolated.

This is an enhanced version of ?larrf that also tries shifts in the middle of the cluster, should there be a large gap, in order to break large clusters into at least two pieces.

## Input Parameters

|          |                                                                                  |
|----------|----------------------------------------------------------------------------------|
| <i>n</i> | The order of the matrix (subblock, if the matrix was split).                     |
| <i>d</i> | Array of size <i>n</i>                                                           |
|          | The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .                 |
| <i>l</i> | Array of size <i>n-1</i>                                                         |
|          | The ( <i>n-1</i> ) subdiagonal elements of the unit bidiagonal matrix <i>L</i> . |

|                  |                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| $l_d$            | Array of size $n-1$                                                                                                                               |
|                  | The $(n-1)$ elements $l[i]*d[i]$ .                                                                                                                |
| $clstrt$         | The index of the first eigenvalue in the cluster.                                                                                                 |
| $clend$          | The index of the last eigenvalue in the cluster.                                                                                                  |
| $clmid1, clmid2$ | The index of a middle eigenvalue pair with large gap.                                                                                             |
| $w$              | Array of size $\geq (clend-clstrt+1)$                                                                                                             |
|                  | The eigenvalue approximations of $LDL^T$ in ascending order. $w[clstrt-1]$ through $w[clend-1]$ form the cluster of relatively close eigenvalues. |
| $wgap$           | Array of size $\geq (clend-clstrt+1)$                                                                                                             |
|                  | The separation from the right neighbor eigenvalue in $w$ .                                                                                        |
| $werr$           | Array of size $\geq (clend-clstrt+1)$                                                                                                             |
|                  | $werr$ contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in $w$ .                                  |
| $spdiam$         | Estimate of the spectral diameter obtained from the Gershgorin intervals                                                                          |
| $clgap1, clgap2$ | Absolute gap on each end of the cluster.                                                                                                          |
|                  | Set by the calling function to protect against shifts too close to eigenvalues outside the cluster.                                               |
| $pivmin$         | The minimum pivot allowed in the Sturm sequence.                                                                                                  |
| $work$           | Workspace array of size $2*n$                                                                                                                     |

## OUTPUT Parameters

|         |                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------|
| $wgap$  | Contains refined values of its input approximations. Very small gaps are unchanged.                          |
| $sigma$ | The shift ( $\sigma$ ) used to form $L_+D_+L_+^T$ .                                                          |
| $dplus$ | Array of size $n$                                                                                            |
|         | The $n$ diagonal elements of the diagonal matrix $D_+$ .                                                     |
| $lplus$ | Array of size $n-1$                                                                                          |
|         | The first $(n-1)$ elements of $lplus$ contain the subdiagonal elements of the unit bidiagonal matrix $L_+$ . |

## Description

?larrv2 computes the eigenvectors of the tridiagonal matrix  $T = LDL^T$  given  $L$ ,  $D$  and approximations to the eigenvalues of  $LDL^T$ . The input eigenvalues should have been computed by [larre2a](#) or by previous calls to ?larrv2.

The major difference between the parallel and the sequential construction of the representation tree is that in the parallel case, not all eigenvalues of a given cluster might be computed locally. Other processors might "own" and refine part of an eigenvalue cluster. This is crucial for scalability. Thus there might be communication necessary before the current level of the representation tree can be parsed.

Please note:

- The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy  $m \geq dou \geq dol \geq 1$ . These parameters are only relevant when both eigenvalues and eigenvectors are computed (steqr2b parameter *jobz* = 'V'). ?larrv2 only computes the eigenvectors corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenvectors belonging to *w*[0] through *w*[*m*-1], only the eigenvectors belonging to eigenvalues *w*[*dol* - 1] through *w*[*dou* - 1] are computed. In this case, only the eigenvalues *dol:dou* are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.
- The additional arguments *vstart*, *finish*, *ndepth*, *parity*, *zoffset* are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable *finish* is non-zero, the computation has ended. All eigenpairs between *dol* and *dou* have been computed. *m* is set to *dou - dol + 1*.
- ?larrv2 needs more workspace in *z* than the sequential slarrv. It is used to store the conformal embedding of the local representation tree.

## Input Parameters

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>                      | The order of the matrix. $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>vl</i> , <i>vu</i>         | Lower and upper bounds of the interval that contains the desired eigenvalues. $vl < vu$ . Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range. <i>vu</i> is currently not used but kept as parameter in case needed.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>d</i>                      | Array of size <i>n</i><br>The <i>n</i> diagonal elements of the diagonal matrix <i>d</i> . On exit, <i>d</i> is overwritten.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>l</i>                      | Array of size <i>n</i><br>The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix <i>L</i> are in elements 0 to $n-2$ of <i>l</i> (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by ?larre. On exit, <i>l</i> is overwritten.                                                                                                                                                                                                                                                                                                                                                                                |
| <i>pivmin</i>                 | The minimum pivot allowed in the sturm sequence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>isplit</i>                 | Array of size <i>n</i><br>The splitting points, at which the matrix <i>T</i> breaks up into blocks. The first block consists of rows/columns 1 to <i>isplit</i> [ 0 ], the second of rows/columns <i>isplit</i> [ 0 ] + 1 through <i>isplit</i> [ 1 ], etc.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>m</i>                      | The total number of input eigenvalues. $0 \leq m \leq n$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>dol</i> , <i>dou</i>       | If you want to compute only selected eigenvectors from all the eigenvalues supplied, you can specify an index range <i>dol:dou</i> . Or else the setting <i>dol=1</i> , <i>dou=m</i> should be applied. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>w</i> . If you want to compute only selected eigenpairs, the columns <i>dol-1</i> to <i>dou+1</i> of the eigenvector space <i>Z</i> contain the computed eigenvectors. All other columns of <i>Z</i> are set to zero.<br><br>If <i>dol</i> > 1, then <i>Z(:,dol-1-zoffset)</i> is used.<br>If <i>dou</i> < <i>m</i> , then <i>Z(:,dou+1-zoffset)</i> is used. |
| <i>needil</i> , <i>neediu</i> | Describe which are the left and right outermost eigenvalues that still need to be included in the computation. These indices indicate whether eigenvalues from other processors are needed to correctly compute the conformally embedded representation tree.<br><br>When $dol \leq needil \leq neediu \leq dou$ , all required eigenvalues are local to the processor and no communication is required to compute its part of the representation tree.                                                                                                                                                                                                                |
| <i>minrgp</i>                 | The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>rto11</i> , <i>rto12</i>   | Parameters for bisection. An interval $[left,right]$ has converged if $right-left < \max( rto11*gap, rto12*\max( left , right ) )$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>w</i>                      | Array of size <i>n</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

The first  $m$  elements of  $w$  contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array  $w$  from ?steqr2a is expected here.) Furthermore, they are with respect to the shift of the corresponding root representation for their block.

*werr*Array of size  $n$ 

The first  $m$  elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in  $w$ .

*wgap*Array of size  $n$ 

The separation from the right neighbor eigenvalue in  $w$ .

*iblock*Array of size  $n$ 

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in  $w$ ;  $iblock[i]=1$  if eigenvalue  $w[i]$  belongs to the first block from the top,  $iblock[i]=2$  if  $w[i]$  belongs to the second block, and so on.

*indexw*Array of size  $n$ 

The indices of the eigenvalues within each block (submatrix). For example:  $indexw[i]=10$  and  $iblock[i]=2$  imply that the  $(i+1)$ -th eigenvalue  $w[i]$  is the 10th eigenvalue in block 2.

*gers*Array of size  $2*n$ 

The  $n$  Gershgorin intervals (the  $i$ -th Gershgorin interval is  $(gers[2*i-2], gers[2*i-1])$ ). The Gershgorin intervals should be computed from the original unshifted matrix.

Not used but kept as parameter for possible future use.

*sdiam*Array of size  $n$ 

The spectral diameters for all unreduced blocks.

*ldz*

The leading dimension of the array  $z$ .  $ldz \geq 1$ , and if `stegr2b` parameter `jobz = 'V'`,  $ldz \geq \max(1,n)$ .

*work*(workspace) array of size  $12*n$ *iwork*(workspace) Array of size  $7*n$ *vstart*

Non-zero on initialization, set to zero afterwards.

*finish*

A flag that indicates whether all eigenpairs have been computed.

*maxcls*

The largest cluster worked on by this processor in the representation tree.

*ndepth*

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

*parity*

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

*zoffset*Offset for storing the eigenpairs when  $z$  is distributed in 1D-cyclic fashion.

## OUTPUT Parameters

The <i>i</i>-th eigenvector is non-zero only in elements <i>isuppz[ 2*i-2 ]</i> through <i>isuppz[ 2*i-1 ]</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>vstart</i>                 | Non-zero on initialization, set to zero afterwards.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>finish</i>                 | A flag that indicates whether all eigenpairs have been computed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>maxcls</i>                 | The largest cluster worked on by this processor in the representation tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>ndepth</i>                 | The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>parity</i>                 | An internal parameter needed for the storage of the clusters on the current level of the representation tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>info</i>                   | <ul style="list-style-type: none"> <li>= 0: successful exit</li> <li>&gt; 0: A problem occurred in <a href="#">?larrv2</a>.</li> <li>&lt; 0: One of the called functions signaled an internal problem.</li> <li>Needs inspection of the corresponding parameter <i>info</i> for further information.</li> <li>=-1: Problem in <a href="#">?larrb2</a> when refining a child's eigenvalues.</li> <li>=-2: Problem in <a href="#">?larrf2</a> when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter <i>minrgp</i> smaller and recompile. However, as the orthogonality of the computed vectors is proportional to <math>1/\minrgp</math>, be aware that decreasing <i>minrgp</i> might be reduce precision.</li> <li>=-3: Problem in <a href="#">?larrb2</a> when refining a single eigenvalue after the Rayleigh correction was rejected.</li> <li>= 5: The Rayleigh Quotient Iteration failed to converge to full accuracy.</li> </ul> |

### ?lasorte

*Sorts eigenpairs by real and complex data types.*

## Syntax

```
void slasorte (float *s , MKL_INT *lds , MKL_INT *j , float *out , MKL_INT *info);
void dlasorte (double *s , MKL_INT *lds , MKL_INT *j , double *out , MKL_INT *info);
```

## Include Files

- mkl\_scalapack.h

## Description

The ?lasortefunction sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This function does no parallel work and makes no calls.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

### ?lasrt2

*Sorts numbers in increasing or decreasing order.*

## Syntax

```
void slasrt2 (char *id , MKL_INT *n , float *d , MKL_INT *key , MKL_INT *info);
void dlasrt2 (char *id , MKL_INT *n , double *d , MKL_INT *key , MKL_INT *info);
```

## Include Files

- mkl\_scalapack.h

## Description

The ?lasrt2 function is modified LAPACK function [?lasrt](#), which sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D'). It uses Quick Sort, reverting to Insertion Sort on arrays of size  $\leq 20$ . The size of STACK limits *n* to about  $2^{32}$ .

## Input Parameters

|            |                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>id</i>  | = 'I': sort <i>d</i> in increasing order;<br>= 'D': sort <i>d</i> in decreasing order.                                                                                                           |
| <i>n</i>   | The length of the array <i>d</i> .                                                                                                                                                               |
| <i>d</i>   | Array of size <i>n</i> .<br>On entry, the array to be sorted.                                                                                                                                    |
| <i>key</i> | Array of size <i>n</i> .<br>On entry, <i>key</i> contains a key to each of the entries in <i>d</i> .<br>Typically, <i>key</i> [ <i>i</i> ] = <i>i</i> +1 for all <i>i</i> = 0, ..., <i>n</i> -1. |

## Output Parameters

|             |                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>d</i>    | On exit, <i>d</i> has been sorted into increasing order<br>( $d[0] \leq \dots \leq d[n - 1]$ )<br>or into decreasing order<br>( $d[0] \geq \dots \geq d[n - 1]$ ),<br>depending on <i>id</i> .                                                                                                        |
| <i>info</i> | = 0: successful exit<br>< 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value.                                                                                                                                                                                            |
| <i>key</i>  | On exit, <i>key</i> is permuted in exactly the same manner as <i>d</i> was permuted from input to output. Therefore, if <i>key</i> [ <i>i</i> ] = <i>i</i> +1 for all <i>i</i> = 0, ..., <i>n</i> -1 on input, <i>d</i> [ <i>i</i> ] on output equals <i>d</i> [ <i>key</i> [ <i>i</i> ]-1] on input. |

### Description

?stegr2 computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix  $T$ . It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version either when only eigenvalues are to be computed, or when only a single processor is used (the sequential-like case).

?stegr2 has been adapted from LAPACK's ?stegr. Please note the following crucial changes.

1. The calling sequence has two additional integer parameters,  $dol$  and  $dou$ , that should satisfy  $m \geq dou \geq dol \geq 1$ . ?stegr2 only computes the eigenpairs corresponding to eigenvalues  $dol$  through  $dou$  in  $w$ , indexed  $dol-1$  through  $dou-1$ . (That is, instead of computing the eigenpairs belonging to  $w[0]$  through  $w[m-1]$ , only the eigenvectors belonging to eigenvalues  $w[dol-1]$  through  $w[dou-1]$  are computed. In this case, only the eigenvalues  $dol$  through  $dou$  are guaranteed to be fully accurate.)
2.  $m$  is not the number of eigenvalues specified by  $range$ , but is  $m = dou - dol + 1$ . This concerns the case where only eigenvalues are computed, but on more than one processor. Thus, in this case  $m$  refers to the number of eigenvalues computed on this processor.
3. The arrays  $w$  and  $z$  might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

| <i>vu</i>               | If <i>range</i> ='V', the lower and upper bounds of the interval to be searched for eigenvalues. $vl < vu$ .<br><br>Not referenced if <i>range</i> = 'A' or 'I'.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>il</i> , <i>iu</i>   | If <i>range</i> ='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in <i>w</i> [ <i>il</i> -1], and largest eigenvalue, to be returned in <i>w</i> [ <i>iu</i> -1].<br><br>$1 \leq il \leq iu \leq n$ , if <i>n</i> > 0.<br><br>Not referenced if <i>range</i> = 'A' or 'V'.                                                                                                                                                                                                                                                                                                   |
| <i>ldz</i>              | The leading dimension of the array <i>z</i> . $ldz \geq 1$ , and if <i>jobz</i> = 'V', then $ldz \geq \max(1,n)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>nzc</i>              | The number of eigenvectors to be held in the array <i>z</i> , storing the matrix <i>Z</i> .<br><br>If <i>range</i> = 'A', then $nzc \geq \max(1,n)$ .<br><br>If <i>range</i> = 'V', then $nzc \geq$ the number of eigenvalues in $(vl, vu]$ .<br><br>If <i>range</i> = 'I', then $nzc \geq iu - il + 1$ .<br><br>If <i>nzc</i> = -1, then a workspace query is assumed; the function calculates the number of columns of the matrix <i>Z</i> that are needed to hold the eigenvectors. This value is returned as the first entry of the <i>z</i> array, and no error message related to <i>nzc</i> is issued. |
| <i>lwork</i>            | The size of the array <i>work</i> . $lwork \geq \max(1, 18 * n)$<br><br>if <i>jobz</i> = 'V', and $lwork \geq \max(1, 12 * n)$ if <i>jobz</i> = 'N'. If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued.                                                                                                                                                                                                 |
| <i>liwork</i>           | The size of the array <i>iwork</i> . $liwork \geq \max(1, 10 * n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8 * n)$ if only the eigenvalues are to be computed.<br><br>If <i>liwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued.                                                                                                                                                          |
| <i>dol</i> , <i>dou</i> | From the eigenvalues <i>w</i> [0] through <i>w</i> [ <i>m</i> -1], only eigenvectors $Z(:, dol)$ to $Z(:, dou)$ are computed.<br><br>If <i>dol</i> > 1, then $Z(:, dol-1 - zoffset)$ is used and overwritten.                                                                                                                                                                                                                                                                                                                                                                                                 |

If  $dou < m$ , then  $Z(:,dou+1-zoffset)$  is used and overwritten.

$zoffset$

Offset for storing the eigenpairs when  $z$  is distributed in 1D-cyclic fashion

## OUTPUT Parameters

$m$

Globally summed over all processors,  $m$  equals the total number of eigenvalues found.  $0 \leq m \leq n$ . If  $range = 'A'$ ,  $m = n$ , and if  $range = 'I'$ ,  $m = iu - il + 1$ . The local output equals  $m = dou - dol + 1$ .

$w$

Array of size  $n$

The first  $m$  elements contain the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed  $dol-1$  through  $dou-1$  are reliable on this processor because the eigenvalue computation is done in parallel. Other processors will hold reliable information on other parts of the  $w$  array. This information is communicated in the ScaLAPACK driver.

$z$

Array of size  $ldz * \max(1,m)$ .

If  $jobz = 'V'$ , and if  $info = 0$ , then the first  $m$  columns of the matrix  $Z$  stored in  $z$  contain some of the orthonormal eigenvectors of the matrix  $T$  corresponding to the selected eigenvalues, with the  $i$ -th column of  $Z$  holding the eigenvector associated with  $w[i-1]$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

Note: the user must ensure that at least  $\max(1,m)$  columns of the matrix are supplied in the array  $z$ ; if  $range = 'V'$ , the exact value of  $m$  is not known in advance and can be computed with a workspace query by setting  $nzc = -1$ , see below.

$isuppz$

array of size  $2*\max(1,m)$

The support of the eigenvectors in  $z$ , i.e., the indices indicating the nonzero elements in  $z$ . The  $i$ -th computed eigenvector is nonzero only in elements  $isuppz[ 2*i-2 ]$  through  $isuppz[ 2*i-1 ]$ . This is relevant in the case when the matrix is split.  $isuppz$  is only set if  $n>2$ .

$work$

On exit, if  $info = 0$ ,  $work[0]$  returns the optimal (and minimal)  $lwork$ .

$iwork$

On exit, if  $info = 0$ ,  $iwork[0]$  returns the optimal  $liwork$ .

$info$

On exit,  $info$

= 0: successful exit

other: if  $info = -i$ , the  $i$ -th argument had an illegal value

if  $info = 10X$ , internal error in ?larre2,

if  $info = 20X$ , internal error in ?larry.

Here, the digit X = ABS(  $iinfo$  ) < 10, where  $iinfo$  is the nonzero error code returned by ?larre2 or ?larry, respectively.

### Description

?stegr2a computes selected eigenvalues and initial representations needed for eigenvector computations in ?stegr2b. It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version when both eigenvalues and eigenvectors are computed in parallel on multiple processors. For this case, ?stegr2a implements the first part of the MRRR algorithm, parallel eigenvalue computation and finding the root RRR. At the end of ?stegr2a, other processors might have a part of the spectrum that is needed to continue the computation locally. Once this eigenvalue information has been received by the processor, the computation can then proceed by calling the second part of the parallel MRRR algorithm, ?stegr2b.

Please note:

- The calling sequence has two additional integer parameters, (compared to LAPACK's stegr), these are *dol* and *dou* and should satisfy  $m \geq dol \geq dol \geq 1$ . These parameters are only relevant for the case *jobz* = 'V'.

Globally invoked over all processors, ?stegr2a computes all the eigenvalues specified by *range*.

?stegr2a locally only computes the eigenvalues corresponding to eigenvalues *dol* through *dou* in *w*, indexed *dol*-1 through *dou*-1. (That is, instead of computing the eigenvectors belonging to *w*[0] through *w*[*m*-1], only the eigenvectors belonging to eigenvalues *w*[*dol*-1] through *w*[*dou*-1] are computed. In this case, only the eigenvalues *dol* through *dou* are guaranteed to be fully accurate.

- *m* is not the number of eigenvalues specified by *range*, but it is  $m = dou - dol + 1$ . Instead, *m* refers to the number of eigenvalues computed on this processor.
- While no eigenvectors are computed in ?stegr2a itself (this is done later in ?stegr2b), the interface

If *jobz* = 'V' then, depending on *range* and *dol*, ?stegr2a might need more workspace in *z* than the original ?stegr. In particular, the arrays *w* and *z* might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

| <i>il</i> , <i>iu</i> | If <i>range</i> ='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in <i>w</i> [ <i>il</i> -1], and largest eigenvalue, to be returned in <i>w</i> [ <i>iu</i> -1]. $1 \leq il \leq iu \leq n$ , if <i>n</i> > 0.<br><br>Not referenced if <i>range</i> = 'A' or 'V'.                                                                                                                                                                                                                                                                                                                       |
| <i>ldz</i>            | The leading dimension of the array <i>z</i> . <i>ldz</i> $\geq 1$ , and if <i>jobz</i> = 'V', then <i>ldz</i> $\geq \max(1,n)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>nzc</i>            | The number of eigenvectors to be held in the array <i>z</i> .<br><br>If <i>range</i> = 'A', then <i>nzc</i> $\geq \max(1,n)$ .<br>If <i>range</i> = 'V', then <i>nzc</i> $\geq$ the number of eigenvalues in ( <i>vl</i> , <i>vu</i> ].<br>If <i>range</i> = 'I', then <i>nzc</i> $\geq iu - il + 1$ .<br><br>If <i>nzc</i> = -1, then a workspace query is assumed; the function calculates the number of columns of the matrix stored in array <i>z</i> that are needed to hold the eigenvectors. This value is returned as the first entry of the <i>z</i> array, and no error message related to <i>nzc</i> is issued. |
| <i>lwork</i>          | The size of the array <i>work</i> . <i>lwork</i> $\geq \max(1,18*n)$ if <i>jobz</i> = 'V', and <i>lwork</i> $\geq \max(1,12*n)$ if <i>jobz</i> = 'N'.<br><br>If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued.                                                                                                                                                                                                      |
| <i>liwork</i>         | The size of the array <i>iwork</i> . <i>liwork</i> $\geq \max(1,10*n)$ if the eigenvectors are desired, and <i>liwork</i> $\geq \max(1,8*n)$ if only the eigenvalues are to be computed.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

If  $liwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the  $iwork$  array, returns this value as the first entry of the  $iwork$  array, and no error message related to  $liwork$  is issued.

$dol, dou$

From all the eigenvalues  $w[0]$  through  $w[m-1]$ , only eigenvalues  $w[dol-1]$  through  $w[dou-1]$  are computed.

## OUTPUT Parameters

$m$

Globally summed over all processors,  $m$  equals the total number of eigenvalues found.  $0 \leq m \leq n$ .

If  $range = 'A'$ ,  $m = n$ , and if  $range = 'I'$ ,  $m = iu - il + 1$ .

The local output equals  $m = dou - dol + 1$ .

$w$

The first  $m$  elements contain approximations to the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed  $dol-1$  through  $dou-1$  are reliable on this processor because the eigenvalue computation is done in parallel. The other entries are very crude preliminary approximations. Other processors hold reliable information on these other parts of the  $w$  array.

This information is communicated in the ScaLAPACK driver.

$z$

Array of size  $ldz * \max(1, m)$ .

?stegr2a does not compute eigenvectors, this is done in ?stegr2b. The argument  $z$  as well as all related other arguments only appear to keep the interface consistent and to signal to the user that this function is meant to be used when eigenvectors are computed.

$work$

On exit, if  $info = 0$ ,  $work[0]$  returns the optimal (and minimal)  $iwork$ .

$iwork$

On exit, if  $info = 0$ ,  $iwork[0]$  returns the optimal  $liwork$ .

$needil, neediu$

The indices of the leftmost and rightmost eigenvalues needed to accurately compute the relevant part of the representation tree. This information can be used to find out which processors have the relevant eigenvalue information needed so that it can be communicated.

$inderr$

$inderr$  points to the place in the work space where the eigenvalue uncertainties (errors) are stored.

$nsplit$

The number of blocks into which  $T$  splits.  $1 \leq nsplit \leq n$ .

$pivmin$

The minimum pivot in the sturm sequence for  $T$ .

$scale$

The scaling factor for the tridiagonal  $T$ .

$wl, wu$

The interval  $(wl, wu]$  contains all the wanted eigenvalues.

It is either given by the user or computed in ?larre2a.

$info$

On exit,  $info = 0$ : successful exit

other: if  $info = -i$ , the  $i$ -th argument had an illegal value

if  $info = 10x$ , internal error in ?larre2a,

Here, the digit  $x = \text{abs}(iinfo) < 10$ , where  $iinfo$  is the nonzero error code returned by `?larre2a`.

## Description

`?stegr2b` should only be called after a call to `?stegr2a`. From eigenvalues and initial representations computed by `?stegr2a`, `?stegr2b` computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. It is potentially invoked multiple times on a given processor because the locally relevant representation tree might depend on spectral information that is "owned" by other processors and might need to be communicated.

Please note:

- The calling sequence has two additional integer parameters, `dol` and `dou`, that should satisfy  $m \geq dou \geq dol \geq 1$ . These parameters are only relevant for the case `jobz = 'V'`. `?stegr2b` only computes the eigenvectors corresponding to eigenvalues `dol` through `dou` in `w`, indexed `dol-1` through `dou-1`. (That is, instead of computing the eigenvectors belonging to `w[0]` through `w[m-1]`, only the eigenvectors belonging to eigenvalues `w[dol-1]` through `w[dou-1]` are computed. In this case, only the eigenvalues `dol` through `dou` are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.)
- The additional arguments `vstart`, `finish`, `ndepth`, `parity`, `zoffset` are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable `finish` is non-zero, the computation has ended. All eigenpairs between `dol` and `dou` have been computed. `m` is set to `dou - dol + 1`.
- `?stegr2b` needs more workspace in `z` than the sequential `?stegr`. It is used to store the conformal embedding of the local representation tree.

Note that only the eigenvalues from the locally relevant part of the representation tree, that is all the clusters that include eigenvalues from <i>dol</i> through <i>dou</i> , are reliable on this processor. (It does not need to know about any others anyway.)                                                              |
| <i>ldz</i>      | The leading dimension of the array <i>z</i> . <i>ldz</i> $\geq 1$ , and if <i>jobz</i> = 'V', then <i>ldz</i> $\geq \max(1, n)$ .                                                                                                                                                                                                                                                                                                                                  |
| <i>nzc</i>      | The number of eigenvectors to be held in the array <i>z</i> , storing the matrix <i>Z</i> .                                                                                                                                                                                                                                                                                                                                                                        |
| <i>lwork</i>    | The size of the array <i>work</i> . <i>lwork</i> $\geq \max(1, 18 * n)$<br>if <i>jobz</i> = 'V', and <i>lwork</i> $\geq \max(1, 12 * n)$ if <i>jobz</i> = 'N'.<br><br>If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued.                                     |
| <i>liwork</i>   | The size of the array <i>iwork</i> . <i>liwork</i> $\geq \max(1, 10 * n)$ if the eigenvectors are desired, and <i>liwork</i> $\geq \max(1, 8 * n)$ if only the eigenvalues are to be computed.<br><br>If <i>liwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued. |
| <i>dol, dou</i> | From the eigenvalues <i>w</i> [0] through <i>w</i> [ <i>m</i> -1], only eigenvectors <i>Z</i> (:, <i>dol</i> ) to <i>Z</i> (:, <i>dou</i> ) are computed.<br><br>If <i>dol</i> > 1, then <i>Z</i> (:, <i>dol</i> -1 - <i>zoffset</i> ) is used and overwritten.                                                                                                                                                                                                    |

If  $dou < m$ , then  $Z(:,dou+1-zoffset)$  is used and overwritten.

|                       |                                                                                                                                                                              |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>needil, neediu</i> | Describes which are the left and right outermost eigenvalues still to be computed. Initially computed by <a href="#">?larre2a</a> , modified in the course of the algorithm. |
| <i>pivmin</i>         | The minimum pivot in the sturm sequence for $T$ .                                                                                                                            |
| <i>scale</i>          | The scaling factor for $T$ . Used for unscaling the eigenvalues at the very end of the algorithm.                                                                            |
| <i>wl, wu</i>         | The interval $(wl, wu]$ contains all the wanted eigenvalues.                                                                                                                 |
| <i>vstart</i>         | Non-zero on initialization, set to zero afterwards.                                                                                                                          |
| <i>finish</i>         | Indicates whether all eigenpairs have been computed.                                                                                                                         |
| <i>maxcls</i>         | The largest cluster worked on by this processor in the representation tree.                                                                                                  |
| <i>ndepth</i>         | The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.                          |
| <i>parity</i>         | An internal parameter needed for the storage of the clusters on the current level of the representation tree.                                                                |
| <i>zoffset</i>        | Offset for storing the eigenpairs when $z$ is distributed in 1D-cyclic fashion.                                                                                              |

## OUTPUT Parameters

|                       |                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>z</i>              | Array of size $ldz * \max(1,m)$<br><br>If $jobz = 'V'$ , and if $info = 0$ , then a subset of the first $m$ columns of the matrix $Z$ , stored in $z$ , contain the orthonormal eigenvectors of the matrix $T$ corresponding to the selected eigenvalues, with the $i$ -th column of $Z$ holding the eigenvector associated with $w[i-1]$ .<br><br>See $dol, dou$ for more information. |
| <i>isuppz</i>         | array of size $2*\max(1,m)$ .<br><br>The support of the eigenvectors in $z$ , i.e., the indices indicating the nonzero elements in $z$ . The $i$ -th computed eigenvector is nonzero only in elements $isuppz[ 2*i-2 ]$ through $isuppz[ 2*i - 1 ]$ . This is relevant in the case when the matrix is split. <i>isuppz</i> is only set if $n > 2$ .                                     |
| <i>work</i>           | On exit, if $info = 0$ , $work[0]$ returns the optimal (and minimal) $lwork$ .                                                                                                                                                                                                                                                                                                          |
| <i>iwork</i>          | On exit, if $info = 0$ , $iwork[0]$ returns the optimal $liwork$ .                                                                                                                                                                                                                                                                                                                      |
| <i>needil, neediu</i> | Modified in the course of the algorithm.                                                                                                                                                                                                                                                                                                                                                |
| <i>indwlc</i>         | Pointer into the workspace location where the local eigenvalue representations are stored. ("Local eigenvalues" are those relative to the individual shifts of the RRRs.)                                                                                                                                                                                                               |
| <i>vstart</i>         | Non-zero on initialization, set to zero afterwards.                                                                                                                                                                                                                                                                                                                                     |
| <i>finish</i>         | Indicates whether all eigenpairs have been computed                                                                                                                                                                                                                                                                                                                                     |
| <i>maxcls</i>         | The largest cluster worked on by this processor in the representation tree.                                                                                                                                                                                                                                                                                                             |

---

|               |                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ndepth</i> | The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.                                                                                                                                                                                                                                              |
| <i>parity</i> | An internal parameter needed for the storage of the clusters on the current level of the representation tree.                                                                                                                                                                                                                                                                                    |
| <i>info</i>   | <p>On exit, <i>info</i></p> <p>= 0: successful exit</p> <p>other: if <i>info</i> = <i>-i</i>, the <i>i</i>-th argument had an illegal value</p> <p>if <i>info</i> = 20<i>x</i>, internal error in <a href="#">?larrv2</a>.</p> <p>Here, the digit <i>x</i> = <math>\text{abs}(\text{iinfo}) &lt; 10</math>, where <i>iinfo</i> is the nonzero error code returned by <a href="#">?larrv2</a></p> |

## ?stein2

*Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.*

### Syntax

```
void sstein2 (MKL_INT *n , float *d , float *e , MKL_INT *m , float *w , MKL_INT
*iblock , MKL_INT *isplit , float *orfac , float *z , MKL_INT *ldz , float *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info);
void dstein2 (MKL_INT *n , double *d , double *e , MKL_INT *m , double *w , MKL_INT
*iblock , MKL_INT *isplit , double *orfac , double *z , MKL_INT *ldz , double *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info);
```

### Include Files

- `mkl_scalapack.h`

### Description

The `?stein2` function is a modified LAPACK function `?stein`. It computes the eigenvectors of a real symmetric tridiagonal matrix *T* corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter *maxits* (currently set to 5).

### Input Parameters

|                                |                                                                                                                                                     |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>                       | The order of the matrix <i>T</i> ( $n \geq 0$ ).                                                                                                    |
| <i>m</i>                       | The number of eigenvectors to be found ( $0 \leq m \leq n$ ).                                                                                       |
| <i>d</i> , <i>e</i> , <i>w</i> | Arrays:                                                                                                                                             |
|                                | <i>d</i> , of size <i>n</i> . The <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> .                                                   |
|                                | <i>e</i> , of size <i>n</i> .                                                                                                                       |
|                                | The ( <i>n</i> -1) subdiagonal elements of the tridiagonal matrix <i>T</i> , in elements 1 to <i>n</i> -1. <i>e</i> [ <i>n</i> -1] need not be set. |

$w$ , of size  $n$ .

The first  $m$  elements of  $w$  contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array  $w$  from [?stebz](#) with ORDER = 'B' is expected here).

The size of  $w$  must be at least  $\max(1, n)$ .

$iblock$

Array of size  $n$ .

The submatrix indices associated with the corresponding eigenvalues in  $w$ ;

$iblock[i] = 1$ , if eigenvalue  $w[i]$  belongs to the first submatrix from the top,

$iblock[i] = 2$ , if eigenvalue  $w[i]$  belongs to the second submatrix, etc. (The output array  $iblock$  from [?stebz](#) is expected here).

$isplit$

Array of size  $n$ .

The splitting points, at which  $T$  breaks up into submatrices. The first submatrix consists of rows/columns 1 to  $isplit[0]$ , the second submatrix consists of rows/columns  $isplit[0]+1$  through  $isplit[1]$ , etc. (The output array  $isplit$  from [?stebz](#) is expected here).

$orfac$

$orfac$  specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within  $orfac^* ||T||$  of each other are to be orthogonalized.

$ldz$

The leading dimension of the output array  $z$ ;  $ldz \geq \max(1, n)$ .

$work$

Workspace array of size  $5n$ .

$iwork$

Workspace array of size  $n$ .

## Output Parameters

$z$

Array of size  $ldz * m$ .

The computed eigenvectors. The eigenvector associated with the eigenvalue  $w[i]$  is stored in the  $(i+1)$ -th column of the matrix  $Z$  represented by  $z$ ,  $i=0, \dots, m-1$ . Any vector that fails to converge is set to its current iterate after  $maxits$  iterations.

$ifail$

Array of size  $m$ .

On normal exit, all elements of  $ifail$  are zero. If one or more eigenvectors fail to converge after  $maxits$  iterations, then their indices are stored in the array  $ifail$ .

$info$

$info = 0$ , the exit is successful.

$info < 0$ : if  $info = -i$ , the  $i$ -th had an illegal value.

$info > 0$ : if  $info = i$ , then  $i$  eigenvectors failed to converge in  $maxits$  iterations. Their indices are stored in the array  $ifail$ .

## Description

The `?dbtf2` function computes an *LU* factorization of a general real/complex  $m$ -by- $n$  band matrix  $A$  without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling [BLAS Routines and Functions](#).

## Input Parameters

|        |                                                                                                                                                                                                                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $m$    | The number of rows of the matrix $A$ ( $m \geq 0$ ).                                                                                                                                                                                                                                             |
| $n$    | The number of columns in $A$ ( $n \geq 0$ ).                                                                                                                                                                                                                                                     |
| $kl$   | The number of sub-diagonals within the band of $A$ ( $kl \geq 0$ ).                                                                                                                                                                                                                              |
| $ku$   | The number of super-diagonals within the band of $A$ ( $ku \geq 0$ ).                                                                                                                                                                                                                            |
| $ab$   | Array of size $ldab * n$ .<br>The matrix $A$ in band storage, in rows $kl+1$ to $2kl+ku+1$ ; rows 1 to $kl$ of the matrix need not be set. The $j$ -th column of $A$ is stored in the array $ab$ as follows: $ab[kl+ku+i-j+(j-1)*ldab] = A(i,j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$ . |
| $ldab$ | The leading dimension of the array $ab$ .<br>$(ldab \geq 2kl + ku + 1)$                                                                                                                                                                                                                          |

## Output Parameters

|        |                                                                                                                                                                                                                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $ab$   | On exit, details of the factorization: $U$ is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$ , and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$ . See the <i>Application Notes</i> below for further details. |
| $info$ | = 0: successful exit                                                                                                                                                                                                                                                                                     |

< 0: if  $\text{info} = -i$ , the  $i$ -th argument had an illegal value,  
> 0: if  $\text{info} = +i$ , the matrix element  $U(i,i)$  is 0. The factorization has been completed, but the factor  $U$  is exactly singular. Division by 0 will occur if you use the factor  $U$  for solving a system of linear equations.

## Application Notes

The band storage scheme is illustrated by the following example, when  $m = n = 6$ ,  $k_1 = 2$ ,  $k_u = 1$ :

**on entry**

|          |          |          |          |          |          |
|----------|----------|----------|----------|----------|----------|
| *        | $a_{12}$ | $a_{23}$ | $a_{34}$ | $a_{45}$ | $a_{56}$ |
| $a_{11}$ | $a_{22}$ | $a_{33}$ | $a_{44}$ | $a_{55}$ | $a_{66}$ |
| $a_{21}$ | $a_{32}$ | $a_{43}$ | $a_{54}$ | $a_{65}$ | *        |
| $a_{31}$ | $a_{42}$ | $a_{53}$ | $a_{64}$ | *        | *        |

**on exit**

|          |          |          |          |          |
|----------|----------|----------|----------|----------|
| *        | $u_{12}$ | $u_{23}$ | $u_{34}$ | $u_{45}$ |
| $u_{11}$ | $u_{22}$ | $u_{33}$ | $u_{44}$ | $u_{55}$ |
| $m_{21}$ | $m_{32}$ | $m_{43}$ | $m_{54}$ | $m_{65}$ |
| $m_{31}$ | $m_{42}$ | $m_{53}$ | $m_{64}$ | *        |

The function does not use array elements marked \*; elements marked + need not be set on entry, but the function requires them to store elements of  $U$ , because of fill-in resulting from the row interchanges.

## Description

The `?dttrf` function computes an *LU* factorization of a real or complex tridiagonal matrix *A* using elimination without partial pivoting.

The factorization has the form  $A = L \cdot U$ , where *L* is a product of unit lower bidiagonal matrices and *U* is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

## Input Parameters

|                                  |                                                                                        |
|----------------------------------|----------------------------------------------------------------------------------------|
| <i>n</i>                         | The order of the matrix <i>A</i> ( $n \geq 0$ ).                                       |
| <i>dl</i> , <i>d</i> , <i>du</i> | Arrays containing elements of <i>A</i> .                                               |
|                                  | The array <i>dl</i> of size $(n-1)$ contains the sub-diagonal elements of <i>A</i> .   |
|                                  | The array <i>d</i> of size <i>n</i> contains the diagonal elements of <i>A</i> .       |
|                                  | The array <i>du</i> of size $(n-1)$ contains the super-diagonal elements of <i>A</i> . |

## Output Parameters

|             |                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dl</i>   | Overwritten by the $(n-1)$ multipliers that define the matrix <i>L</i> from the <i>LU</i> factorization of <i>A</i> .                                                                                                                                                                                                                                                                                 |
| <i>d</i>    | Overwritten by the <i>n</i> diagonal elements of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i> .                                                                                                                                                                                                                                                                  |
| <i>du</i>   | Overwritten by the $(n-1)$ elements of the first super-diagonal of <i>U</i> .                                                                                                                                                                                                                                                                                                                         |
| <i>info</i> | = 0: successful exit<br>< 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value,<br>> 0: if <i>info</i> = <i>i</i> , the matrix element <i>U</i> ( <i>i</i> , <i>i</i> ) is exactly 0. The factorization has been completed, but the factor <i>U</i> is exactly singular. Division by 0 will occur if you use the factor <i>U</i> for solving a system of linear equations. |

## Description

The ?dttrsfunction solves one of the following systems of linear equations:

$$L^*X = B, L^T*X = B, \text{ or } L^H*X = B,$$

$$U^*X = B, U^T*X = B, \text{ or } U^H*X = B$$

with factors of the tridiagonal matrix  $A$  from the  $LU$  factorization computed by [?dttrf](#).

## Input Parameters

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>      | Specifies whether to solve with $L$ or $U$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>trans</i>     | Must be 'N' or 'T' or 'C'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                  | Indicates the form of the equations:<br>If <i>trans</i> = 'N', then $A^*X=B$ is solved for $X$ (no transpose).<br>If <i>trans</i> = 'T', then $A^T*X = B$ is solved for $X$ (transpose).<br>If <i>trans</i> = 'C', then $A^H*X = B$ is solved for $X$ (conjugate transpose).                                                                                                                                                                                                                                          |
| <i>n</i>         | The order of the matrix $A$ ( $n \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>nrhs</i>      | The number of right-hand sides, that is, the number of columns in the matrix $B$ ( $nrhs \geq 0$ ).                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>dl,d,du,b</i> | The array <i>dl</i> of size ( $n - 1$ ) contains the ( $n - 1$ ) multipliers that define the matrix $L$ from the $LU$ factorization of $A$ .<br>The array <i>d</i> of size $n$ contains $n$ diagonal elements of the upper triangular matrix $U$ from the $LU$ factorization of $A$ .<br>The array <i>du</i> of size ( $n - 1$ ) contains the ( $n - 1$ ) elements of the first super-diagonal of $U$ .<br>On entry, the array <i>b</i> of size <i>ldb</i> * <i>nrhs</i> contains the right-hand side of matrix $B$ . |
| <i>ldb</i>       | The leading dimension of the array <i>b</i> ; <i>ldb</i> $\geq \max(1, n)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Output Parameters

|             |                                                 |
|-------------|-------------------------------------------------|
| <i>b</i>    | Overwritten by the solution matrix $X$ .        |
| <i>info</i> | If <i>info</i> =0, the execution is successful. |

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## Description

The ?pttrsv function solves one of the triangular systems:

$L^T X = B$ , or  $L^H X = B$  for real flavors,

or

$L^H X = B$ , or  $L^H X = B$ ,

$U^T X = B$ , or  $U^H X = B$  for complex flavors,

where  $L$  (or  $U$  for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix  $A$  such that

$A = L^T D L^H$  (computed by [spttrf/dpttrf](#))

or

$A = U^H D U$  or  $A = L^H D L^H$  (computed by [cpttrf/zpttrf](#)).

## Input Parameters

*uplo*

Must be 'U' or 'L'.

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix  $A$  is stored and the form of the factorization:

If  $uplo = 'U'$ ,  $e$  is the superdiagonal of  $U$ , and  $A = U^H D U$  or  $A = L^H D L^H$ ;

if  $uplo = 'L'$ ,  $e$  is the subdiagonal of  $L$ , and  $A = L^T D L^H$ .

The two forms are equivalent, if  $A$  is real.

|              |                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>trans</i> | Specifies the form of the system of equations:<br>for real flavors:<br><br>if <i>trans</i> = 'N': $L \cdot X = B$ (no transpose)<br>if <i>trans</i> = 'T': $L^T \cdot X = B$ (transpose)<br>for complex flavors:<br><br>if <i>trans</i> = 'N': $U \cdot X = B$ or $L \cdot X = B$ (no transpose)<br>if <i>trans</i> = 'C': $U^H \cdot X = B$ or $L^H \cdot X = B$ (conjugate transpose). |
| <i>n</i>     | The order of the tridiagonal matrix $A$ . $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                   |
| <i>nrhs</i>  | The number of right hand sides, that is, the number of columns of the matrix $B$ . $nrhs \geq 0$ .                                                                                                                                                                                                                                                                                       |
| <i>d</i>     | array of size $n$ . The $n$ diagonal elements of the diagonal matrix $D$ from the factorization computed by <a href="#">?pttrf</a> .                                                                                                                                                                                                                                                     |
| <i>e</i>     | array of size $(n-1)$ . The $(n-1)$ off-diagonal elements of the unit bidiagonal factor $U$ or $L$ from the factorization computed by <a href="#">?pttrf</a> . See <i>uplo</i> .                                                                                                                                                                                                         |

## ?steqr2

Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

## Syntax

```
void ssteqr2 (char *compz , MKL_INT *n , float *d , float *e , float *z , MKL_INT *ldz , MKL_INT *nr , float *work , MKL_INT *info);
void dsteqr2 (char *compz , MKL_INT *n , double *d , double *e , double *z , MKL_INT *ldz , MKL_INT *nr , double *work , MKL_INT *info);
```

## Include Files

- mkl\_scalapack.h

## Description

The `?steqr2` function is a modified version of LAPACK function `?steqr`. The `?steqr2` function computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. `?steqr2` is modified from `?steqr` to allow each ScaLAPACK process running `?steqr2` to perform updates on a distributed matrix  $Q$ . Proper usage of `?steqr2` can be gleaned from examination of ScaLAPACK function `p?syev`.

## Input Parameters

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## ?trmv

Performs matrix-vector operations.

## Syntax

```
void strmv (const char* uplo, const MKL_INT* n, const float* t, const MKL_INT* ldt,
float* x, const MKL_INT* incx, const float* y, const MKL_INT* incy, float* w, const
MKL_INT* incw, const float* z, const MKL_INT* incz);

void dtrmv (const char* uplo, const MKL_INT* n, const double* t, const MKL_INT* ldt,
double* x, const MKL_INT* incx, const double* y, const MKL_INT* incy, double* w, const
MKL_INT* incw, const double* z, const MKL_INT* incz);

void ctrmv (const char* uplo, const MKL_INT* n, const MKL_Complex8* t, const MKL_INT* ldt,
MKL_Complex8* x, const MKL_INT* incx, const MKL_Complex8* y, const MKL_INT* incy,
MKL_Complex8* w, const MKL_INT* incw, const MKL_Complex8* z, const MKL_INT* incz);

void ztrmv (const char* uplo, const MKL_INT* n, const MKL_Complex16* t, const MKL_INT* ldt,
MKL_Complex16* x, const MKL_INT* incx, const MKL_Complex16* y, const MKL_INT* incy,
MKL_Complex16* w, const MKL_INT* incw, const MKL_Complex16* z, const MKL_INT* incz);
```

## Include Files

- mkl\_scalapack.h

## Description

?trmv performs the matrix-vector operations as follows:

strmv and dtrmv:  $x := T * y$ , and  $w := T * z$

ctrmv and ztrmv:  $x := \text{conjg}(T) * y$ , and  $w := T * z$ ,

where *x* is an *n* element vector and *T* is an *n*-by-*n* upper or lower triangular matrix.

## Input Parameters

*uplo*

On entry, *uplo* specifies whether the matrix is an upper or lower triangular matrix as follows:

*uplo* = 'U' or 'u'

*A* is an upper triangular matrix.

*uplo* = 'L' or 'l'

*A* is a lower triangular matrix.

Unchanged on exit.

*n*

On entry, *n* specifies the order of the matrix *A*. *n* must be at least zero.

Unchanged on exit.

*t*

Array of size ( *ldt*, *n* ).

Before entry with *uplo* = 'U' or 'u', the leading *n*-by-*n* upper triangular part of the array *t* must contain the upper triangular matrix and the strictly lower triangular part of *t* is not referenced.

Before entry with *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *t* must contain the lower triangular matrix and the strictly upper triangular part of *t* is not referenced.

*ldt*

On entry, *lda* specifies the first dimension of *A* as declared in the calling (sub) program. *lda* must be at least  $\max( 1, n )$ .

Unchanged on exit.

*incx*

On entry, *incx* specifies the increment for the elements of *x*. *incx* must not be zero.

Unchanged on exit.

*y*

Array of size at least (  $1 + ( n - 1 ) * \text{abs}( \text{incy} )$  ).

Before entry, the incremented array *y* must contain the *n* element vector *y*.

Unchanged on exit.

*incy*

On entry, *incy* specifies the increment for the elements of *y*. *incy* must not be zero.

Unchanged on exit.

*incw*

On entry, *incw* specifies the increment for the elements of *w*. *incw* must not be zero.

Unchanged on exit.

*z*

Array of size at least (  $1 + ( n - 1 ) * \text{abs}( \text{incz} )$  ).

Before entry, the incremented array *z* must contain the *n* element vector *z*.

Unchanged on exit.

*incz*

On entry, *incz* specifies the increment for the elements of *z*. *incz* must not be zero.

Unchanged on exit.

## pilaenv

Returns the positive integer value of the logical blocking size.

### Syntax

```
MKL_INT pilaenv (const MKL_INT *ictxt , const char *prec);
```

### Include Files

- mkl\_pblas.h

### Description

*pilaenv* returns the positive integer value of the logical blocking size. This value is machine and precision specific. This version provides a logical blocking size which should give good though not optimal performance on many of the currently available distributed-memory concurrent computers. You are encouraged to modify this subroutine to set this tuning parameter for your particular machine.

### Input Parameters

|              |                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ictxt</i> | On entry, <i>ictxt</i> specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of <i>ictxt</i> is local.                                                                                                                                                                                         |
| <i>prec</i>  | On input, <i>prec</i> specifies the precision for which the logical block size should be returned as follows:<br><br><i>prec</i> = 'S' or 's' single precision real,<br><i>prec</i> = 'D' or 'd' double precision real,<br><i>prec</i> = 'C' or 'c' single precision complex,<br><i>prec</i> = 'Z' or 'z' double precision complex,<br><i>prec</i> = 'I' or 'i' integer. |

### Application Notes

Before modifying this routine to tune the library performance on your system, be aware of the following:

1. The value this function returns must be strictly larger than zero,

2. If you are planning to link your program with different instances of the library (for example, on a heterogeneous machine), you *must* compile each instance of the library with exactly the same version of this routine for obvious interoperability reasons.

## pilaenvx

*Called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment.*

---

### Syntax

```
MKL_INT pilaenvx (const MKL_INT* ictxt, const MKL_INT* ispec, const char* name, const
char* opts, const MKL_INT* n1, const MKL_INT* n2, const MKL_INT* n3, const MKL_INT*
```

### Include Files

- mkl.h

### Description

pilaenvx is called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment. See *ispec* for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

### Input Parameters

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ictxt</i> | (local input)On entry, <i>ictxt</i> specifies the BLACS context handle, indicating the global context of the operation. = 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by `?gelsd` and `?gesdd`).  
=10: IEEE NaN arithmetic can be trusted not to trap.  
=11: infinity arithmetic can be trusted not to trap.  
12 <= *ispec* <= 16:  
p?hseqr or one of its subroutines, see `piparmq` for detailed explanation.  
17 <= *ispec* <= 22:  
Parameters for pb?trord/p?hseqr (not all), as follows:  
=17: maximum number of concurrent computational windows;  
=18: number of eigenvalues/bulges in each window;  
=19: computational window size;  
=20: minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations;  
=21: width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form;  
=22: the maximum number of eigenvalues moved together over a process border;  
=23: the number of processors involved in Aggressive Early Deflation (AED);  
=99: Maximum iteration chunksize in OpenMP parallelization.

*name*

(global input)

The name of the calling subroutine, in either upper case or lower case.

*opts*(global input) The character options to the subroutine name, concatenated into a single character string. For example, `uplo = 'U'`, `trans = 'T'`, and `diag = 'N'` for a triangular routine would be specified as `opts = 'UTN'`.*n1, n2, n3, and n4*

(global input) Problem dimensions for the subroutine name; these may not all be required.

## Output Parameters

*result*

(global output)

>= 0: the value of the parameter specified by *ispec*.< 0: if `pilaenvx = -k`, the *k*-th argument had an illegal value.

## Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

- opts* is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by *ispec*.

2. The problem dimensions  $n_1$ ,  $n_2$ ,  $n_3$ , and  $n_4$  are specified in the order that they appear in the argument list for `name`.  $n_1$  is used first,  $n_2$  second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by `ilaenv` is checked for validity in the calling subroutine. For example, `ilaenv` is used to retrieve the optimal block size for `strtri` as follows:

```
NB = ilaenv(1, 'STRTRI', UPTO // DIAG, N, -1, -1, -1);
if(NB<=1) {
 NB = MAX(1, N);
}
```

The same conventions hold for this ScaLAPACK-style variant.

## pjlaenv

*Called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment.*

### Syntax

```
MKL_INT pjlaenv (const MKL_INT* ictxt, const MKL_INT* ispec, const char* name, const
char* opts, const MKL_INT* n1, const MKL_INT* n2, const MKL_INT* n3, const MKL_INT*
n4);
```

### Include Files

- `mkl.h`

### Description

`pjlaenv` is called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment. See `ispec` for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

### Input Parameters

`ispec` (global input) Specifies the parameter to be returned as the value of `pjlaenv`.

- = 1: the data layout blocksize;
- = 2: the panel blocking factor;
- = 3: the algorithmic blocking factor;
- = 4: execution path control;
- = 5: maximum size for direct call to the LAPACK routine.

`name` (global input) The name of the calling subroutine, in either upper case or lower case.

`opts` (global input) The character options to the subroutine name, concatenated into a single character string. For example, `uplo = 'U'`, `trans = 'T'`, and `diag = 'N'` for a triangular routine would be specified as `opts = 'UTN'`.

*n<sub>1</sub>, n<sub>2</sub>, n<sub>3</sub>, and n<sub>4</sub>*(global input) Problem dimensions for the subroutine name; these may not all be required. At present, only *n<sub>1</sub>* is used, and it (*n<sub>1</sub>*) is used only for 'TTRD'.

## Output Parameters

*result*

(global or local output)

>= 0: the value of the parameter specified by *ispec*.< 0: if *pjlaenv* = -*k*, the *k*-th argument had an illegal value. Most parameters set via a call to *pjlaenv* must be identical on all processors and hence *pjlaenv* will return the same value to all processors (i.e. global output). However some, in particular, the panel blocking factor can be different on each processor and hence *pjlaenv* can return different values on different processors (i.e. local output).

## Application Notes

The following conventions have been used when calling *pjlaenv* from the ScaLAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n<sub>1</sub>, n<sub>2</sub>, n<sub>3</sub>, and n<sub>4</sub>* are specified in the order that they appear in the argument list for name. *n<sub>1</sub>* is used first, *n<sub>2</sub>* second, and so on, and unused problem dimensions are passed a value of -1.
  - a. The parameter value returned by *pjlaenv* is checked for validity in the calling subroutine. For example, *pjlaenv* is used to retrieve the optimal blocksize for STRTRI as follows:

```
NB = pjlaenv(1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1);
IF(NB>=1) {
 NB = MAX(1, N);
}
```

*pjlaenv* is patterned after *ilaenv* and keeps the same interface in anticipation of future needs, even though *pjlaenv* is only sparsely used at present in ScaLAPACK. Most ScaLAPACK codes use the input data layout blocking factor as the algorithmic blocking factor - hence there is no need or opportunity to set the algorithmic or data decomposition blocking factor. *pXYYtevx.f* and *pXYYtgvx.f* and *pXYYttrd.f* are the only codes which call *pjlaenv*. *pXYYtevx.f* and *pXYYtgvx.f* redistribute the data to the best data layout for each transformation. *pXYYttrd.f* uses a data layout blocking factor of 1.

## ScaLAPACK Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

### ScaLAPACK Utility Functions and Routines

| Routine Name | Data Types | Description                                                                                           |
|--------------|------------|-------------------------------------------------------------------------------------------------------|
| p?labad      | s,d        | Returns the square root of the underflow and overflow thresholds if the exponent-range is very large. |
| p?lachkieee  | s,d        | Performs a simple check for the features of the IEEE standard.                                        |
| p?lamch      | s,d        | Determines machine parameters for floating-point arithmetic.                                          |
| p?lasnbt     | s,d        | Computes the position of the sign bit of a floating-point number.                                     |
| descinit     | N/A        | Initializes the array descriptor for distributed matrix.                                              |

| Routine Name           | Data Types | Description                                                                          |
|------------------------|------------|--------------------------------------------------------------------------------------|
| <a href="#">numroc</a> | N/A        | Computes the number of rows or columns of a distributed matrix owned by the process. |

## p?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

## Syntax

```
void pslabad (MKL_INT *ictxt , float *small , float *large);
void pdlabad (MKL_INT *ictxt , double *small , double *large);
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?labad` function takes as input the values computed by `p?lamch` for underflow and overflow, and returns the square root of each of these values if the log of `large` is sufficiently large. This function is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `p?lamch`. This function is needed because `p?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this function performs a global minimization and maximization on these values, to support heterogeneous computing networks.

## Input Parameters

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <code>ictxt</code> | (global).                                                               |
|                    | The BLACS context handle in which the computation takes place.          |
| <code>small</code> | (local).                                                                |
|                    | On entry, the underflow threshold as computed by <code>p?lamch</code> . |
| <code>large</code> | (local).                                                                |
|                    | On entry, the overflow threshold as computed by <code>p?lamch</code> .  |

## Output Parameters

|                    |                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>small</code> | (local).                                                                                                                  |
|                    | On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of <code>small</code> , otherwise unchanged. |
| <code>large</code> | (local).                                                                                                                  |
|                    | On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of <code>large</code> , otherwise unchanged. |

### p?lachkieee

*Performs a simple check for the features of the IEEE standard.*

## Syntax

```
void pslachkieee (MKL_INT *isieee , float *rmax , float *rmin);
void pdlachkieee (MKL_INT *isieee , float *rmax , float *rmin);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lachkieee` function performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, `p?lachkieee` may not return.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

## Input Parameters

|                   |                                                         |
|-------------------|---------------------------------------------------------|
| <code>rmax</code> | (local).                                                |
|                   | The overflow threshold (= <code>?lamch ('O')</code> ).  |
| <code>rmin</code> | (local).                                                |
|                   | The underflow threshold (= <code>?lamch ('U')</code> ). |

## Output Parameters

|                     |                                                                                                                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>isieee</code> | (local).                                                                                                                                                                                                                               |
|                     | On exit, <code>isieee = 1</code> implies that all the features of the IEEE standard that we rely on are implemented. On exit, <code>isieee = 0</code> implies that some the features of the IEEE standard that we rely on are missing. |

### p?lamch

*Determines machine parameters for floating-point arithmetic.*

## Syntax

```
float pslamch (MKL_INT *ictxt , char *cmach);
double pdlamch (MKL_INT *ictxt , char *cmach);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lamch` function determines single precision machine parameters.

## Input Parameters

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## ***p?lasnbt***

*Computes the position of the sign bit of a floating-point number.*

## Syntax

```
void pslasnbt (MKL_INT *ieflag);
void pdlasnbt (MKL_INT *ieflag);
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lasnbt` function finds the position of the signbit of a single/double precision floating point number. This function assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

## Output Parameters

`ieflag`

This flag indicates the position of the signbit of any single/double precision floating point number.

`ieflag = 0`, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.

`ieflag = 1` indicates that the signbit is the 32-nd bit for a single precision function.

In the case of a double precision function:

`ieflag = 1` indicates that the signbit is the 32-nd bit (Big Endian).

`ieflag = 2` indicates that the signbit is the 64-th bit (Little Endian).

## See Also

## descinit

Initializes the array descriptor for distributed matrix.

## Syntax

```
void descinit (MKL_INT *desc, const MKL_INT *m, const MKL_INT *n, const MKL_INT *mb,
const MKL_INT *nb, const MKL_INT *irsrc, const MKL_INT *icsrc, const MKL_INT *ictxt,
const MKL_INT *lld, MKL_INT *info);
```

## Description

The `descinit` function initializes the array descriptor for distributed matrix.

## Input Parameters

`desc` (global) array of dimension `DLEN_`. The array descriptor of a distributed matrix to be set.

`m` (global input) The number of rows in the distributed matrix. `M >= 0`.

`n` (global input) The number of columns in the distributed matrix. `N >= 0`.

`mb` (global input) The blocking factor used to distribute the rows of the matrix. `MB >= 1`.

`nb` (global input) The blocking factor used to distribute the columns of the matrix. `NB >= 1`.

|              |                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>lrsrc</i> | (global input) The process row over which the first row of the matrix is distributed. $0 \leq IRSRC < NPROW$ .                                                                                                                                                                         |
| <i>lcsrc</i> | (global input) The process column over which the first column of the matrix is distributed. $0 \leq ICSRC < NPCOL$ .                                                                                                                                                                   |
| <i>ictxt</i> | (global input) The BLACS context handle, indicating the global context of the operation on the matrix. The context itself is global.                                                                                                                                                   |
| <i>lld</i>   | (local input) The leading dimension of the local array storing the local blocks of the distributed matrix. $LLD \geq \text{MAX}(1, \text{LOCr}(M))$ . $\text{LOCr}()$ denotes the number of rows of a global dense matrix that the process in a grid receives after data distributing. |

## Output Parameters

|             |                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------|
| <i>info</i> | (output)<br>= 0: successful exit<br>< 0: if INFO = -i, the i-th argument had an illegal value |
|-------------|-----------------------------------------------------------------------------------------------|

## numroc

*Computes the number of rows or columns of a distributed matrix owned by the process.*

---

## Syntax

```
MKL_INT numroc (const MKL_INT *n, const MKL_INT *nb, const MKL_INT *iproc, const
MKL_INT *srcproc, const MKL_INT *nprocs);
```

## Description

The `numroc` function computes the number of rows or columns of a distributed matrix owned by the process.

## Input Parameters

|                |                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------|
| <i>n</i>       | (global input) The number of rows/columns in distributed matrix.                                               |
| <i>nb</i>      | (global input) Block size, size of the blocks the distributed matrix is split into.                            |
| <i>iproc</i>   | (local input) The coordinate of the process whose local array row or column is to be determined.               |
| <i>srcproc</i> | (global input) The coordinate of the process that possesses the first row or column of the distributed matrix. |
| <i>nprocs</i>  | (global input) The total number processes over which the matrix is distributed.                                |

## Output Parameters

|             |                                          |
|-------------|------------------------------------------|
| <i>info</i> | (output) Value returned by the function. |
|-------------|------------------------------------------|

## ScaLAPACK Redistribution/Copy Routines

This section describes ScaLAPACK redistribution/copy routines. Summary information about these routines is given in the following table:

### ScaLAPACK Redistribution/Copy Routines

| Routine Name             | Data Types    | Description                                                        |
|--------------------------|---------------|--------------------------------------------------------------------|
| <a href="#">p?gemr2d</a> | s, d, c, z, i | Copies a submatrix from one general rectangular matrix to another. |
| <a href="#">p?trmr2d</a> | s, d, c, z, i | Copies a submatrix from one trapezoidal matrix to another.         |

## Description

The [p?gemr2d](#) function copies the indicated matrix or submatrix of *A* to the indicated matrix or submatrix of *B*. It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With [p?trmr2d](#), these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix *A* in context *A* (distributed over process grid *A*) and copy it to a matrix or submatrix *B* in context *B* (distributed over process grid *B*).

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context  $A$  is disjoint from context  $B$ . The general rules for which parameters need to be set are:

- All calling processes must have the correct  $m$  and  $n$ .
- Processes in context  $A$  must correctly define all parameters describing  $A$ .
- Processes in context  $B$  must correctly define all parameters describing  $B$ .
- Processes which are not members of context  $A$  must pass  $ctxt\_a = -1$  and need not set other parameters describing  $A$ .
- Processes which are not members of context  $B$  must pass  $ctxt\_b = -1$  and need not set other parameters describing  $B$ .

Because of its generality, `p?gemr2d` can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScalAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with  $dtype\_a = 1$ .

#### Input Parameters

|          |                                                                                                                                                                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $m$      | (global) The number of rows of matrix $A$ to be copied ( $m \geq 0$ ).                                                                                                                                                                                             |
| $n$      | (global) The number of columns of matrix $A$ to be copied ( $n \geq 0$ ).                                                                                                                                                                                          |
| $a$      | (local)<br>Pointer into the local memory to array of size $l1d\_a * LOCc(ja+n-1)$ containing the source matrix $A$ .                                                                                                                                               |
| $ia, ja$ | (global) The row and column indices in the array $A$ indicating the first row and the first column, respectively, of the submatrix of $A$ to copy. $1 \leq ia \leq total\_rows\_in\_a - m + 1, 1 \leq ja \leq total\_columns\_in\_a - n + 1$ .                     |
| $desca$  | (global and local) array of size $dlen\_a$ . The array descriptor for the distributed matrix $A$ .<br><br>Only $dtype\_a = 1$ is supported, so $dlen\_a = 9$ .<br><br>If the calling process is not part of the context of $A$ , $ctxt\_a$ must be equal to $-1$ . |
| $ib, jb$ | (global) The row and column indices in the array $B$ indicating the first row and the first column, respectively, of the submatrix $B$ to which to copy the matrix. $1 \leq ib \leq total\_rows\_in\_b - m + 1, 1 \leq jb \leq total\_columns\_in\_b - n + 1$ .    |
| $descb$  | (global and local) array of size $dlen\_b$ . The array descriptor for the distributed matrix $B$ .<br><br>Only $dtype\_b = 1$ is supported, so $dlen\_b = 9$ .                                                                                                     |

If the calling process is not part of the context of  $B$ ,  $\text{ctxt}_b$  must be equal to  $-1$ .

$\text{ictxt}$  (global).

The context encompassing at least the union of all processes in context  $A$  and context  $B$ . All processes in the context  $\text{ictxt}$  must call this function, even if they do not own a piece of either matrix.

## Output Parameters

$b$  Pointer into the local memory to array of size  $\text{lld}_b * \text{LOCc}(\text{jb} + n - 1)$ . Overwritten by the submatrix from  $A$ .

## Description

The `p?trmr2d` function copies the indicated matrix or submatrix of  $A$  to the indicated matrix or submatrix of  $B$ . It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With `p?gemr2d`, these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix  $A$  in context  $A$  (distributed over process grid  $A$ ) and copy it to a matrix or submatrix  $B$  in context  $B$  (distributed over process grid  $B$ ).

The `p?trmr2d` function assumes the matrix or submatrix to be trapezoidal. Only the upper or lower part is copied, and the other part is unchanged.

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context *A* is disjoint from context *B*. The general rules for which parameters need to be set are:

- All calling processes must have the correct *m* and *n*.
- Processes in context *A* must correctly define all parameters describing *A*.
- Processes in context *B* must correctly define all parameters describing *B*.
- Processes which are not members of context *A* must pass *ctxt\_a* = -1 and need not set other parameters describing *A*.
- Processes which are not members of context *B* must pass *ctxt\_b* = -1 and need not set other parameters describing *B*.

Because of its generality, `p?trmr2d` can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with *dtype\_* = 1.

## Sparse Solver Routines

Intel® oneAPI Math Kernel Library (oneMKL) sparse solver algorithms for solving real or complex, symmetric, structurally symmetric or nonsymmetric, positive definite, indefinite or Hermitian square sparse linear system of algebraic equations.

The terms and concepts required to understand the use of the Intel® oneAPI Math Kernel Library (oneMKL) sparse solver routines are discussed in the [Appendix "Linear Solvers Basics"](#). If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

See the description of

- the direct sparse solver based on PARDISO\*, which is referred to here as [Intel MKL PARDISO](#);
- the alternative interface for the direct sparse solver, which is referred to here as the [DSS interface](#);
- [iterative sparse solvers \(ISS\)](#) based on the reverse communication interface (RCI);
- [preconditioners](#) based on the incomplete LU factorization technique.
- a direct sparse [solver](#) based on QR decomposition.

## oneMKL PARDISO - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver.

The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode

techniques [Schenk00-2]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [Schenk00, Schenk01, Schenk02, Schenk03]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

The following table lists the names of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO routines and describes their general use.

#### oneMKL PARDISO Routines

| Routine                                   | Description                                                                                                                   |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">pardisoinit</a>               | Initializes Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with default parameters depending on the matrix type.          |
| <a href="#">pardiso</a>                   | Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.                         |
| <a href="#">pardiso_64</a>                | Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version. |
| <a href="#">mkl_pardiso_pivot</a>         | Replaces routine which handles Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with user-defined routine.           |
| <a href="#">pardiso_getdiag</a>           | Returns diagonal elements of initial and factorized matrix.                                                                   |
| <a href="#">pardiso_export</a>            | Places pointers dedicated for sparse representation of requested matrix into MKL PARDISO.                                     |
| <a href="#">pardiso_handle_store</a>      | Store internal structures from <code>pardiso</code> to a file.                                                                |
| <a href="#">pardiso_handle_restore</a>    | Restore <code>pardiso</code> internal structures from a file.                                                                 |
| <a href="#">pardiso_handle_delete</a>     | Delete files with <code>pardiso</code> internal structure data.                                                               |
| <a href="#">pardiso_handle_store_64</a>   | Store internal structures from <code>pardiso_64</code> to a file.                                                             |
| <a href="#">pardiso_handle_restore_64</a> | Restore <code>pardiso_64</code> internal structures from a file.                                                              |
| <a href="#">pardiso_handle_delete_64</a>  | Delete files with <code>pardiso_64</code> internal structure data.                                                            |

The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver supports a wide range of real and complex sparse matrix types (see the figure below).

---

border\_top

## Sparse Matrices That Can Be Solved with the oneMKL PARDISO Solver

The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

To find code examples that use Intel® oneAPI Math Kernel Library (oneMKL) PARDISO routines to solve systems of linear equations, unzip theC archive file in the `examples` folder of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory. Code examples will be in the `examples/solverc/source` folder.

### Supported Matrix Types

The analysis steps performed by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO depend on the structure of the input matrix  $A$ .

#### Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation  $P$  based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel® oneAPI Math Kernel Library (oneMKL)), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of  $PAP^T = LL^T$  for symmetric positive-definite matrices, or  $PAP^T = LDL^T$  for symmetric indefinite matrices. The solver uses diagonal pivoting, or  $1 \times 1$  and  $2 \times 2$  Bunch-Kaufman pivoting for symmetric indefinite matrices. An approximation of  $X$  is found by forward and backward substitution and optional iterative refinement.

Whenever numerically acceptable  $1 \times 1$  and  $2 \times 2$  pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix  $A$  that, if permuted close to the diagonal, permit the factorization process

to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

#### Structurally Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation  $P$  followed by the parallel numerical factorization of  $PAP^T = QLU^T$ . The solver uses partial pivoting in the supernodes and an approximation of  $X$  is found by forward and backward substitution and optional iterative refinement.

#### Nonsymmetric Matrices

The solver first computes a nonsymmetric permutation  $P_{MPS}$  and scaling matrices  $D_r$  and  $D_c$  with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation  $P$  based on the matrix  $P_{MPS}A + (P_{MPS}A)^T$  followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_rAD_cP$$

with supernode pivoting matrices  $Q$  and  $R$ . When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of

$$\text{alpha} = \text{eps} * \|A2\|_{\infty},$$

where  $\text{eps}$  is the machine precision,  $A2 = P^*P_{MPS}^*D_r^*A^*D_c^*P$ , and  $\|A2\|_{\infty}$  is the infinity norm of  $A$ . Any tiny pivots encountered during elimination are set to the sign  $(1_{II}) * \text{eps} * \|A2\|_{\infty}$ , which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

## Sparse Data Storage

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO stores sparse data in several formats:

- CSR3: The 3-array variation of the compressed sparse row format described in [Three Array Variation of CSR Format](#).
- BSR3: The three-array variation of the block compressed sparse row format described in [Three Array Variation of BSR Format](#). Use `iparm[36]` to specify the block size.
- VBSR: Variable BSR format. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO analyzes the matrix provided in CSR3 format and converts it into an internal structure which can improve performance for matrices with a block structure. Use `iparm[36] = -t` ( $0 < t \leq 100$ ) to specify use of internal VBSR format and to set the degree of similarity required to combine elements of the matrix. For example, if you set `iparm[36] = -80`, two rows of the input matrix are combined when their non-zero patterns are 80% or more similar.

**NOTE**

Intel® oneAPI Math Kernel Library (oneMKL) supports only the VBSR format for real and symmetric positive definite or indefinite matrices ( $mtype = 2$  or  $mtype = -2$ ).

Intel® oneAPI Math Kernel Library (oneMKL) supports these features for all matrix types as long as  $iparm[23] = 1$ :

- $iparm[30] > 0$ : Partial solution
- $iparm[35] > 0$ : Schur complement
- $iparm[59] > 0$ : OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO

---

For all storage formats, the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO parameter  $ja$  is used for the  $columns$  array,  $ia$  is used for  $rowIndex$ , and  $a$  is used for  $values$ . The algorithms in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO require column indices  $ja$  to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or nonsymmetric matrices the diagonal elements which are equal to zero are not necessary.

**Caution**

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO column indices  $ja$  must be in increasing order per row. You can validate the sparse matrix structure with the matrix checker ( $iparm[26]$ )

**NOTE**

While the presence of zero diagonal elements for symmetric matrices is not required, you should explicitly set zero diagonal elements for symmetric matrices. Otherwise, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO creates internal copies of arrays  $ia$ ,  $ja$ , and  $a$  full of diagonal elements, which require additional memory and computational time. However, the memory and time required the diagonal elements in internal arrays is usually not significant compared to the memory and the time required to factor and solve the matrix.

| Product and Performance Information                                                                                                                            |  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Performance varies by use, configuration and other factors. Learn more at <a href="http://www.Intel.com/PerformanceIndex">www.Intel.com/PerformanceIndex</a> . |  |
| Notice revision #20201201                                                                                                                                      |  |

**Storage of Matrices**

By default, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO stores data in RAM. This is referred to as In-Core (IC) mode. However, you can specify that Intel® oneAPI Math Kernel Library (oneMKL) PARDISO store matrices on disk by setting  $iparm[59]$ . This mode is called the Out-of-Core (OOC) mode.

You can set the following parameters for the OOC mode.

| Parameter/Environment Variable Name    | Description                                                      |
|----------------------------------------|------------------------------------------------------------------|
| <code>MKL_PARDISO_OOC_PATH</code>      | Directory for storing data created in the OOC mode.              |
| <code>MKL_PARDISO_OOC_FILE_NAME</code> | Full file name (incl. path) which will be used for the OOC files |

| Parameter/Environment Variable Name | Description                                                                                         |
|-------------------------------------|-----------------------------------------------------------------------------------------------------|
| MKL_PARDISO_OOC_MAX_CORE_SIZE       | Maximum size of RAM (in megabytes) available for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO |
| MKL_PARDISO_OOC_MAX_SWAP_SIZE       | Maximum swap size (in megabytes) available for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO   |
| MKL_PARDISO_OOC_KEEP_FILE           | A flag which determines whether temporary data files will be deleted or stored                      |

By default, the current working directory is used in the OOC mode as a directory path for storing data. All work arrays will be stored in files named `ooc_temp` with different extensions. When `MKL_PARDISO_OOC_FILE_NAME` is not set and `MKL_PARDISO_OOC_PATH` is set, the names for the created files will contain `<path>/mkl_pardiso` or `<path>\mkl_pardiso` depending on the OS. Setting `MKL_PARDISO_OOC_FILE_NAME=<filename>` will override the path which could have been set in `MKL_PARDISO_OOC_PATH`. In this case `<filename>` will be used for naming the OOC files.

By default, `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 (MB) and `MKL_PARDISO_OOC_MAX_SWAP_SIZE` is 0.

---

#### NOTE

Do not set the sum of `MKL_PARDISO_OOC_MAX_CORE_SIZE` and `MKL_PARDISO_OOC_MAX_SWAP_SIZE` greater than the size of the RAM plus the size of the swap memory. Be sure to allow enough free memory for the operating system and any other processes which need to be running.

---

By default, all temporary data files will be deleted. For keeping them it is required to set `MKL_PARDISO_OOC_KEEP_FILE` to 0.

OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variables `MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`.

For setting parameters of OOC mode either environment variables or a configuration file can be used. When the last option is chosen, by default the name of the file is `pardiso_ooc.cfg` and it should be placed in the working directory. If needed, the user can set the path to the configuration file using environmental variables `MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`. These variables specify the path and filename as follows:

- Linux\* OS and OS X\*: `<MKL_PARDISO_OOC_CFG_PATH>/<MKL_PARDISO_OOC_CFG_FILE_NAME>`
- Windows\* OS: `<MKL_PARDISO_OOC_CFG_PATH>\<MKL_PARDISO_OOC_CFG_FILE_NAME>`

An example of the configuration file:

```
MKL_PARDISO_OOC_PATH = <path>
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

---

#### Caution

The maximum length of the path lines in the configuration files is 1000 characters.

---

Alternatively, the OOC parameters can be set as environment variables via command line.

For Linux\* OS and OS X\*:

```
export MKL_PARDISO_OOC_PATH = <path>
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows\* OS:

```
set MKL_PARDISO_OOC_PATH = <path>
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where <path> should follow the OS naming convention.

## Direct-Iterative Preconditioning for Nonsymmetric Linear Systems

The solver uses a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but with an identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses a numerical factorization and applies the factors in a preconditioned Krylov Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to nonsymmetric matrices in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. You can select the method using the *iparm[3]* input parameter. The *iparm[19]* parameter returns the error status after running Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

## Single and Double Precision Computations

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, which is especially important for input matrices with large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made less precisely, only some systems of equations can be solved accurately enough using single precision.

## Separate Forward and Backward Substitution

The solver execution step (see *parameterphase* = 33 below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal. This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix  $A$  (*mtype* = 2) is factored by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as  $A = L \cdot L^T$ . In this case the solution of the system  $A \cdot x = b$  can be found as sequence of substitutions:  $L \cdot y = b$  (forward substitution, *phase* = 331) and  $L^T \cdot x = y$  (backward substitution, *phase* = 333).

A real nonsymmetric matrix  $A$  (*mtype* = 11) is factored by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as  $A = L \cdot U$ . In this case the solution of the system  $A \cdot x = b$  can be found by the following sequence:  $L \cdot y = b$  (forward substitution, *phase* = 331) and  $U \cdot x = y$  (backward substitution, *phase* = 333).

Solving a system with a real symmetric indefinite matrix  $A$  (*mtype* = -2) is slightly different from the cases above. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factors this matrix as  $A = LDL^T$ , and the solution of the system  $A \cdot x = b$  can be calculated as the following sequence of substitutions:  $L \cdot y = b$  (forward

substitution,  $\text{phase} = 331$ ),  $D^*v=y$  (diagonal substitution,  $\text{phase} = 332$ ), and finally  $L^T x=v$  (backward substitution,  $\text{phase} = 333$ ). Diagonal substitution makes sense only for symmetric indefinite matrices ( $mtype = -2, -4, 6$ ). For matrices of other types a solution can be found as described in the first two examples.

### **Caution**

The number of refinement steps ([iparm\[7\]](#)) must be set to zero if a solution is calculated with separate substitutions ( $\text{phase} = 331, 332, 333$ ), otherwise Intel® oneAPI Math Kernel Library (oneMKL) PARDISO produces the wrong result.

---

### **NOTE**

Different pivoting ([iparm\[20\]](#)) produces different  $LDL^T$  factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch-Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step ( $\text{phase}=33$ ) regardless of the pivoting used.

---

## Callback Function for Pivoting Control

In-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO allows you to control pivoting with a callback routine, [mkl\\_pardiso\\_pivot](#). You can then use the [pardiso\\_getdiag](#) routine to access the diagonal elements. Set [iparm\[55\]](#) to 1 in order to use the callback functionality.

## Low Rank Update

Use low rank update to accelerate the factorization step in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO when you use multiple matrices with identical structure and similar values. After calling [pardiso](#) in the usual manner for factorization ( $\text{phase} = 12, 13, 22$ , or  $23$ ) for some matrix  $A_1$ , low rank update can be applied to the factorization step ( $\text{phase} = 22$  or  $23$ ) of some matrix  $A_2$  with identical structure.

To use the low rank update feature, set [iparm\[38\]](#) = 1 while also setting [iparm\[23\]](#) = 10. Additionally, supply an array that lists the values in  $A_2$  that are different from  $A_1$  using the [perm](#) parameter as outlined in the [pardiso perm](#) parameter description.

### **Important**

Low rank update can only be called for matrices with the exact same pattern of nonzero values. As such, the value of the [mtype](#), [ia](#), [ja](#), and [iparm\[23\]](#) parameters should also be identical. In general, the low rank factorization should be called with the same parameters as the preceding factorization step for the same internal data structure handle (except for array [a](#), [iparm\[38\]](#), and [perm](#)).

Low rank update does not currently support Intel TBB threading. In this case, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO defaults to full factorization instead.

Low rank update cannot be used in combination with a user-supplied permutation vector - in other words, you must use the default values of [iparm\[4\]](#) = 0, [iparm\[30\]](#) = 0, and [iparm\[35\]](#) = 0. Additionally, [iparm\[3\]](#), [iparm\[5\]](#), [iparm\[27\]](#), [iparm\[36\]](#), [iparm\[55\]](#), and [iparm\[59\]](#) must all be set to the default value of 0.

---

## [pardiso](#)

*Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.*

---

## Syntax

```
void pardiso (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT *mnum, const
MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a, const MKL_INT
*ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT *iparm, const
MKL_INT *msglvl, void *b, void *x, MKL_INT *error);
```

## Include Files

- mkl.h

## Description

The pardiso routine calculates the solution of a set of sparse linear equations

$$A^*X = B$$

with single or multiple right-hand sides, using a parallel  $LU$ ,  $LDL$ , or  $LL^T$  factorization, where  $A$  is an  $n$ -by- $n$  matrix, and  $X$  and  $B$  are  $n$ -by- $nrhs$  vectors or matrices.

---

### Notes

- This routine supports usage of the `mkl_progress` with OpenMP, TBB, and sequential threading. See `mkl_progress` for details. The case of `iparm[23]=10` does not support this feature.
  - If `iparm[26]` is set to 1 (Matrix checker), Intel® oneAPI Math Kernel Library PARDISO uses the auxiliary routine `sparse_matrix_checker` to check integer arrays `ia` and `ja`. `sparse_matrix_checker` has its own set of error values (from 21 to 24) that are returned in the event of an unsuccessful matrix check. For more details, refer to the `sparse_matrix_checker` documentation.

Notice revision #20201201

## Input Parameters

|                 |                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pt</code> | Array with size of 64.<br>Handle to internal data structure. The entries must be set to zero prior to the first call to <code>pardiso</code> . Unique for factorization. |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

---

### Caution

After the first call to `pardiso` do not directly modify `pt`, as that could cause a serious memory leak.

---

Use the `pardiso_handle_store` or `pardiso_handle_store_64` routine to store the content of `pt` to a file. Restore the contents of `pt` from the file using `pardiso_handle_restore` or `pardiso_handle_restore_64`. Use `pardiso_handle_store` and `pardiso_handle_restore` with `pardiso`, and `pardiso_handle_store_64` and `pardiso_handle_restore_64` with `pardiso_64`.

*maxfct* Maximum number of factors with identical sparsity structure that must be kept in memory at the same time. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data structure management of the solver.

pardiso can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers *pt*.

*mnum* Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be:  $1 \leq mnum \leq maxfct$ .

In most applications this value is 1.

*mtype* Defines the matrix type, which influences the pivoting method. The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver supports the following matrices:

|    |                                         |
|----|-----------------------------------------|
| 1  | real and structurally symmetric         |
| 2  | real and symmetric positive definite    |
| -2 | real and symmetric indefinite           |
| 3  | complex and structurally symmetric      |
| 4  | complex and Hermitian positive definite |
| -4 | complex and Hermitian indefinite        |
| 6  | complex and symmetric                   |
| 11 | real and nonsymmetric                   |
| 13 | complex and nonsymmetric                |

*phase* Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement

This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see [Separate Forward and Backward Substitution](#)).

- Memory release phase (*phase*= 0 or *phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

| <i>phase</i> | <b>Solver Execution Steps</b> |
|--------------|-------------------------------|
|--------------|-------------------------------|

|    |          |
|----|----------|
| 11 | Analysis |
|----|----------|

| <i>phase</i> | <b>Solver Execution Steps</b>                                               |
|--------------|-----------------------------------------------------------------------------|
| 12           | Analysis, numerical factorization                                           |
| 13           | Analysis, numerical factorization, solve, iterative refinement              |
| 22           | Numerical factorization                                                     |
| 23           | Numerical factorization, solve, iterative refinement                        |
| 33           | Solve, iterative refinement                                                 |
| 331          | like <i>phase</i> =33, but only forward substitution                        |
| 332          | like <i>phase</i> =33, but only diagonal substitution (if available)        |
| 333          | like <i>phase</i> =33, but only backward substitution                       |
| 0            | Release internal memory for <i>L</i> and <i>U</i> matrix number <i>mnum</i> |
| -1           | Release all internal memory for all matrices                                |

If *iparm*[35] = 0, phases 331, 332, and 333 perform this decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & L_{22} \end{bmatrix} \begin{bmatrix} D_{11} & 0 \\ 0 & D_{22} \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & U_{22} \end{bmatrix}$$

If *iparm*[35] = 2, phases 331, 332, and 333 perform a different decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & S \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & I \end{bmatrix}$$

You can supply a custom implementation for phase 332 instead of calling *pardiso*. For example, it can be implemented with dense LAPACK functionality. Custom implementation also allows you to substitute the matrix *S* with your own.

---

#### NOTE

For very large Schur complement matrices use LAPACK functionality to compute the Schur complement vector instead of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO phase 332 implementation.

---

*n*  
Number of equations in the sparse linear systems of equations  $A^*X = B$ .  
Constraint:  $n > 0$ .

*a*  
Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of *ja* for each row.

For CSR3 format, the size of  $a$  is the same as that of  $ja$ . Refer to the  $values$  array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format the size of  $a$  is the size of  $ja$  multiplied by the square of the block size. Refer to the  $values$  array description in [Three Array Variation of BSR Format](#) for more details.

---

**NOTE**

If you set  $iparm[36]$  to a negative value, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO converts the data from CSR3 format to an internal variable BSR (VBSR) format. See [Sparse Data Storage](#).

---

$ia$

Array, size  $(n+1)$ .

For CSR3 format,  $ia[i]$  ( $i < n$ ) points to the first column index of row  $i$  in the array  $ja$ . That is,  $ia[i]$  gives the index of the element in array  $a$  that contains the first non-zero element from row  $i$  of  $A$ . The last element  $ia[n]$  is taken to be equal to the number of non-zero elements in  $A$ , plus one. Refer to  $rowIndex$  array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format,  $ia[i]$  ( $i < n$ ) points to the first column index of row  $i$  in the array  $ja$ . That is,  $ia[i]$  gives the index of the element in array  $a$  that contains the first non-zero block from row  $i$  of  $A$ . The last element  $ia[n]$  is taken to be equal to the number of non-zero blocks in  $A$ , plus one. Refer to  $rowIndex$  array description in [Three Array Variation of BSR Format](#) for more details.

The array  $ia$  is accessed in all phases of the solution process.

Indexing of  $ia$  is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter  $iparm[34]$ .

$ja$

For CSR3 format, array  $ja$  contains column indices of the sparse matrix  $A$ . It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal elements are stored (even if they are zeros) in the list of non-zero elements in  $a$  and  $ja$ . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for  $columns$  array in [Three Array Variation of CSR Format](#).

For BSR3 format, array  $ja$  contains column indices of the sparse matrix  $A$ . It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal blocks are stored (even if they are zeros) in the list of non-zero blocks in  $a$  and  $ja$ . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for  $columns$  array in [Three Array Variation of BSR Format](#).

The array  $ja$  is accessed in all phases of the solution process.

Indexing of  $ja$  is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter  $iparm[34]$ .

*perm*

Array, size ( $n$ ). Depending on the value of  $iparm[4]$  and  $iparm[30]$ , holds the permutation vector of size  $n$ , specifies elements used for computing a partial solution, or specifies differing values of the input matrices for low rank update.

- If  $iparm[4] = 1$ ,  $iparm[30] = 0$ , and  $iparm[35] = 0$ ,  $perm$  specifies the fill-in reducing ordering to the solver. Let  $A$  be the original matrix and  $C = P^*A^*P^T$  be the permuted matrix. Row (column)  $i$  of  $C$  is the  $perm[i]$  row (column) of  $A$ . The array  $perm$  is also used to return the permutation vector calculated during fill-in reducing ordering stage.

---

**NOTE**

Be aware that setting  $iparm[4] = 1$  prevents use of a parallel algorithm for the solve step.

- If  $iparm[4] = 2$ ,  $iparm[30] = 0$ , and  $iparm[35] = 0$ , the permutation vector computed in phase 11 is returned in the  $perm$  array.
- If  $iparm[4] = 0$ ,  $iparm[30] > 0$ , and  $iparm[35] = 0$ ,  $perm$  specifies elements of the right-hand side to use or of the solution to compute for a partial solution.
- If  $iparm[4] = 0$ ,  $iparm[30] = 0$ , and  $iparm[35] > 0$ ,  $perm$  specifies elements for a Schur complement.
- If  $iparm[38] = 1$ ,  $perm$  specifies values that differ in  $A$  for low rank update (see [Low Rank Update](#)). The size of the array must be at least  $2*ndiff + 1$ , where  $ndiff$  is the number of values of  $A$  that are different. The values of  $perm$  should be:

```
 $perm = \{ndiff, row_index1, column_index1, row_index2,$
 $column_index2, \dots, row_index_ndiff, column_index_ndiff\}$
```

where  $row\_index_m$  and  $column\_index_m$  are the row and column indices of the  $m$ -th differing non-zero value in matrix  $A$ . The row and column index pairs can be in any order, but must use zero-based indexing regardless of the value of  $iparm[34]$ .

See [iparm\[4\]](#), [iparm\[30\]](#), and [iparm\[38\]](#) for more details.

Indexing of  $perm$  is one-based by default, but unless  $iparm[38] = 1$  it can be changed to zero-based by setting the appropriate value to the parameter [iparm\[34\]](#).

*nrhs*

Number of right-hand sides that need to be solved for.

*iparm*

Array, size (64). This array is used to pass various parameters to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and to return some useful information after execution of the solver.

See [pardiso iparm Parameter](#) for more details about the  $iparm$  parameters.

*msglvl*

Message level information. If  $msglvl = 0$  then pardiso generates no output, if  $msglvl = 1$  the solver prints statistical information to the screen.

*b*

Array, size ( $n*nrhs$ ). On entry, contains the right-hand side vector/matrix  $B$ , which is placed in memory contiguously. The  $b[+k*nrhs]$  element must hold the  $i$ -th component of  $k$ -th right-hand side vector. Note that  $b$  is only accessed in the solution phase.

## Output Parameters

(See also [Intel MKL PARDISO Parameters in Tabular Form](#).)

*pt*

Handle to internal data structure.

*perm*

See the Input Parameter description of the *perm* array.

*iparm*

On output, some *iparm* values report information such as the numbers of non-zero elements in the factors.

See [pardiso iparm Parameter](#) for more details about the *iparm* parameters.

*b*

On output, the array is replaced with the solution if *iparm*[5] = 1.

*x*

Array, size ( $n * nrhs$ ). If *iparm*[5]=0 it contains solution vector/matrix  $X$ , which is placed contiguously in memory. The  $x[i + k*n]$  element must hold the  $i$ -th component of the  $k$ -th solution vector. Note that *x* is only accessed in the solution phase.

*error*

The error indicator according to the below table:

| <b>error</b> | <b>Information</b>                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | no error                                                                                                                                                                                                                                                                                                                                                                                  |
| -1           | input inconsistent                                                                                                                                                                                                                                                                                                                                                                        |
| -2           | not enough memory                                                                                                                                                                                                                                                                                                                                                                         |
| -3           | reordering problem                                                                                                                                                                                                                                                                                                                                                                        |
| -4           | Zero pivot, numerical factorization or iterative refinement problem. If the error appears during the solution phase, try to change the pivoting perturbation ( <i>iparm</i> [9]) and also increase the number of iterative refinement steps. If it does not help, consider changing the scaling, matching and pivoting options ( <i>iparm</i> [10], <i>iparm</i> [12], <i>iparm</i> [20]) |
| -5           | unclassified (internal) error                                                                                                                                                                                                                                                                                                                                                             |
| -6           | reordering failed (matrix types 11 and 13 only)                                                                                                                                                                                                                                                                                                                                           |
| -7           | diagonal matrix is singular                                                                                                                                                                                                                                                                                                                                                               |
| -8           | 32-bit integer overflow problem                                                                                                                                                                                                                                                                                                                                                           |
| -9           | not enough memory for OOC                                                                                                                                                                                                                                                                                                                                                                 |
| -10          | error opening OOC files                                                                                                                                                                                                                                                                                                                                                                   |
| -11          | read/write error with OOC files                                                                                                                                                                                                                                                                                                                                                           |

## pardisoinit

Initialize Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with default parameters in accordance with the matrix type.

### Syntax

```
void pardisoinit (_MKL_DSS_HANDLE_t pt, const MKL_INT *mtype, MKL_INT *iparm);
```

### Include Files

- mkl.h

### Description

This function initializes the solver handle *pt* for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with zero values (as needed for the very first call of *pardiso*) and sets default *iparm* values in accordance with the matrix type *mtype*.

The recommended way is to avoid using *pardisoinit* and to initialize *pt* and set the values of the *iparm* array manually as the default parameters might not be the best for a particular use case.

An alternative method to set default *iparm* values is to call *pardiso* in the analysis phase with *iparm*(1)=0. In this case, the solver handle *pt* must be initialized with zero values.

The *pardisoinit* routine initializes only the in-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. Switching to the out-of-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as well as changing default *iparm* values can be done after the call to *pardisoinit* but before the first call to *pardiso*.

The *pardisoinit* routine cannot be used together with the *pardiso\_64* routine.

### Input Parameters

|              |                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>mtype</i> | Matrix type. Based on this value <i>pardisoinit</i> chooses default values for the <i>iparm</i> array. Refer to the section <a href="#">oneMKL PARDISO Parameters in Tabular Form</a> for more details about the default values of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Output Parameters

|           |                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------|
| <i>pt</i> | Array of size 64. Handle to internal data structure. The <i>pardisoinit</i> routine nullifies the array <i>pt</i> . |
|-----------|---------------------------------------------------------------------------------------------------------------------|

**NOTE**

It is very important that *pt* is initialized with zero before the first call of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. After that first call you must never modify the array, because it could cause a serious memory leak or a crash.

---

*iparm*

Array of size 64. This array is used to set various options for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and to return some useful information after execution of the solver. The *pardisoinit* routine fills in the *iparm* array with the default values. Refer to the section [oneMKL PARDISO Parameters in Tabular Form](#) for more details about the default values of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

**[pardiso\\_64](#)**

*Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.*

---

**Syntax**

```
void pardiso_64 (_MKL_DSS_HANDLE_t pt, const long long int *maxfct, const long long int *mnum, const long long int *mtype, const long long int *phase, const long long int *n, const void *a, const long long int *ia, const long long int *ja, long long int *perm, const long long int *nrhs, long long int *iparm, const long long int *msglvl, void *b, void *x, long long int *error);
```

**Include Files**

- mkl.h

**Description**

*pardiso\_64* is an alternative ILP64 (64-bit integer) version of the [pardiso](#) routine (see [Description](#) section for more details). The interface of *pardiso\_64* is the same as the interface of *pardiso*, but it accepts and returns all integer data as `long long int`.

Use *pardiso\_64* when *pardiso* for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel® oneAPI Math Kernel Library (oneMKL) functionality. In other words, if you use 64-bit integer version (*pardiso\_64*), you do not need to re-link your applications with ILP64 libraries. Take into account that *pardiso\_64* may perform slower than regular *pardiso* on the reordering and symbolic factorization phase.

**NOTE**

*pardiso\_64* is supported only in the 64-bit libraries. If *pardiso\_64* is called from the 32-bit libraries, it returns `error == -12`.

---

**NOTE**

This routine supports the Progress Routine feature. See [Progress Function](#) for details.

---

## Input Parameters

The input parameters of `pardiso_64` are the same as the input parameters of `pardiso`, but `pardiso_64` accepts all integer data as `long long int`.

## Output Parameters

The output parameters of `pardiso_64` are the same as the [output parameters of `pardiso`](#), but `pardiso_64` returns all integer data as `long long int`.

### `mkl_pardiso_pivot`

*Replaces routine which handles Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with user-defined routine.*

## Syntax

```
void mkl_pardiso_pivot (const void *ai, void *bi, const void *eps);
```

## Include Files

- `mkl.h`

## Description

The `mkl_pardiso_pivot` routine allows you to handle diagonal elements which arise during numerical factorization that are zero or near zero. By default, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO determines that a diagonal element `bi` is a pivot if `bi < eps`, and if so, replaces it with `eps`. But you can provide your own routine to modify the resulting factorized matrix in case there are small elements on the diagonal during the factorization step.

---

### NOTE

To use this routine, you must set `iparm[55]` to 1 before the main `pardiso` loop.

---

---

### NOTE

The matrix types `mtype=2` (symmetric positive-definite matrix) and `mtype=4` (complex and Hermitian positive definite) are not supported, because the Cholesky factorization without pivoting is used for these matrix types.

---

## Input Parameters

|                  |                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>ai</code>  | Diagonal element of initial matrix corresponding to pivot element.                                                        |
| <code>bi</code>  | Diagonal element of factorized matrix that could be chosen as a pivot element.                                            |
| <code>eps</code> | Scalar to compare with diagonal of factorized matrix. On input equal to parameter described by <a href="#">iparm[9]</a> . |

## Output Parameters

|                 |                                                                              |
|-----------------|------------------------------------------------------------------------------|
| <code>bi</code> | In case element is chosen as a pivot, value with which to replace the pivot. |
|-----------------|------------------------------------------------------------------------------|

## pardiso\_getdiag

Returns diagonal elements of initial and factorized matrix.

---

### Syntax

```
void pardiso_getdiag (const _MKL_DSS_HANDLE_t pt, void *df, void *da, const MKL_INT *mnum, MKL_INT *error);
```

### Include Files

- mkl.h

### Description

This routine returns the diagonal elements of the initial and factorized matrix for a real or Hermitian matrix.

---

#### NOTE

In order to use this routine, you must set `iparm[55]` to 1 before the main `pardiso` loop.

If `iparm[23]` is set to 10 (an improved two-level factorization algorithm for nonsymmetric matrices), Intel® oneAPI Math Kernel Library PARDISO will automatically use the classic algorithm for factorization.

---

### Input Parameters

|             |                                                                                                                                                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>pt</i>   | Array with a size of 64. Handle to internal data structure for the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver. The entries must be set to zero prior to the first call to <code>pardiso</code> . Unique for factorization.                                                                         |
| <i>mnum</i> | Indicates the actual matrix for the solution phase of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver. With this scalar you can define the diagonal elements of the factorized matrix that you want to obtain. The value must be: $1 \leq mnum \leq maxfct$ . In most applications this value is 1. |

### Output Parameters

|           |                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------|
| <i>df</i> | Array with a dimension of <i>n</i> . Contains diagonal elements of the factorized matrix after factorization. |
|-----------|---------------------------------------------------------------------------------------------------------------|

---

#### NOTE

Elements of *df* correspond to diagonal elements of matrix *L* computed during phase 22. Because during phase 22 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO makes additional permutations to improve stability, it is possible that array *df* is not in line with the *perm* array computed during phase 11.

---

|           |                                                                                        |
|-----------|----------------------------------------------------------------------------------------|
| <i>da</i> | Array with a dimension of <i>n</i> . Contains diagonal elements of the initial matrix. |
|-----------|----------------------------------------------------------------------------------------|

|              |                      |
|--------------|----------------------|
| <i>error</i> | The error indicator. |
|--------------|----------------------|

| <b>error</b> | <b>Information</b>                                                                  |
|--------------|-------------------------------------------------------------------------------------|
| 0            | no error                                                                            |
| -1           | Diagonal information not turned on before pardiso main loop ( <i>iparm</i> [55]=0). |

## pardiso\_export

Places pointers dedicated for sparse representation of a requested matrix (values, rows, and columns) into MKL PARDISO

### Syntax

```
void pardiso_export (const _MKL_DSS_HANDLE_t pt, void* values, MKL_INT* rows, MKL_INT* columns, MKL_INT* step, MKL_INT* iparm, MKL_INT* error);
```

### Include Files

- mkl.h

### Description

This auxiliary routine places pointers dedicated for sparse representation of a requested matrix (values, rows, and columns) into MKL PARDISO. The matrix will be stored in the three-array variant of the compressed sparse row (CSR3 format) with 0-based indexing.

#### NOTE

Currently, this routine can be used only for a sparse Schur complement matrix. All parameters related to the Schur complement matrix (perm, iparm) must be set before the reordering stage of MKL PARDISO (phase = 11) is called.

### Input Parameters

*pt* Array with a size of 64. Handle to internal data structure for the Intel® MKL PARDISO solver. The entries must be set to zero prior to the first call to pardiso. Unique for factorization.

*iparm* This array is used to pass various parameters to Intel® MKL PARDISO and to return some useful information after execution of the solver.

*step* Stage indicator. These are the currently supported values:

| <b>Step value</b> | <b>Notes</b>                                                                                                                                                                                       |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                 | Used to place pointers related to a Schur complement matrix in MKL PARDISO. The routine with <i>step</i> equal to 1 must be called between the reordering and factorization phases of MKL PARDISO. |
| -1                | Used to clean the internal handle.                                                                                                                                                                 |

## Input/Output Parameters

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>values</i>  | Parameter type: input/output parameter.<br><br>This array contains the non-zero elements of the requested matrix.                                                                                                                                                                                                                                                                                                                                                |
| <i>rows</i>    | Parameter type: input/output parameter.<br><br>Array of size $(size + 1)$<br><br>For CSR3 format, $rows[i]$ ( $i < size$ ) points to the first column index of row $i$ in the array <i>columns</i> ; that is, $rows[i]$ gives the index of the element in the array <i>values</i> that contains the first non-zero element from row $i$ of the sparse matrix. The last element, $rows[size]$ , is equal to the number of non-zero elements in the sparse matrix. |
| <i>columns</i> | Parameter type: input/output parameter.<br><br>This array contains the column indices for the non-zero elements of the requested matrix.                                                                                                                                                                                                                                                                                                                         |
| <i>error</i>   | Parameter type: output parameter.<br><br>The error status: <ul style="list-style-type: none"><li>• 0 indicates no error.</li><li>• 1 indicates inconsistent input data.</li></ul>                                                                                                                                                                                                                                                                                |

## Usage Example

The following C-style example demonstrates how to use the `pardiso_export` routine to get the sparse representation (that is, three-array CSR format) of a Schur complement matrix.

```
#include "mkl.h"

/*
 * Call the reordering phase of MKL PARDISO with iparm[35] set to -1 in
 * order to compute the Schur complement matrix only, or -2 to compute all
 * factorization arrays. perm array indices related to the Schur complement
 * matrix must be set to 1.
 */
phase = 11;
for (i = 0; i < schur_size; i++) { perm[i] = 1.; }
iparm[35] = -1;
pardiso(pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs,
 iparm, &msglvl, b, x, &error);

/*
 * After the reordering phase, iparm[35] will contain the number of non-zero
 * elements for the Schur complement matrix. Arrays dedicated to the sparse
 * representation of the Schur complement matrix must be allocated before
 * the factorization stage of MKL PARDISO is called.
 */
schur_nnz = iparm[35];
schur_rows = (MKL_INT *) mkl_malloc(schur_size+1, ALIGNMENT);
schur_columns = (MKL_INT *) mkl_malloc(schur_nnz , ALIGNMENT);
schur_values = (DATA_TYPE *) mkl_malloc(schur_nnz , ALIGNMENT);

/*
 * Call to the pardiso_export routine with step equal to 1 in order to put
```

```

 * pointers related to the three-array CSR format into MKL PARDISO:
 */
pardiso_export(pt, schur_values, schur_ia, schur_ja, &step, iparm, &error);

/*
 * Call the factorization phase of PARDISO with iparm[35] equal to -1 or -2
 * to compute the Schur complement matrix:
 */
phase = 22;
iparm[35] = -1;
pardiso(pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs,
 iparm, &mmsglvl, b, x, &error);

/*
 * After the factorization stage, schur_values, schur_rows, and
 * schur_columns will contain the Schur complement matrix in CSR3 format.
 */

```

## [pardiso\\_handle\\_store](#)

*Store internal structures from pardiso to a file.*

### Syntax

```
void pardiso_handle_store (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

### Include Files

- mkl.h

### Description

This function stores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures to a file, allowing you to store Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures between the stages of the `pardiso` routine. The `pardiso_handle_restore` routine can restore the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures from the file.

### Input Parameters

|                      |                                                                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pt</code>      | Array with a size of 64. Handle to internal data structure.                                                                                                                                                                                                |
| <code>dirname</code> | String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named <code>handle.pds</code> in the directory. |

### Output Parameters

|                    |                                    |
|--------------------|------------------------------------|
| <code>pt</code>    | Handle to internal data structure. |
| <code>error</code> | The error indicator.               |

| <b>error</b> | <b>Information</b>            |
|--------------|-------------------------------|
| 0            | No error.                     |
| -2           | Not enough memory.            |
| -10          | Cannot open file for writing. |

| <b>error</b> | <b>Information</b>           |
|--------------|------------------------------|
| -11          | Error while writing to file. |
| -13          | Wrong file format.           |

## **pardiso\_handle\_restore**

*Restore pardiso internal structures from a file.*

---

### **Syntax**

```
void pardiso_handle_restore (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

### **Include Files**

- mkl.h

### **Description**

This function restores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures from a file. This allows you to restore Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures stored by `pardiso_handle_store` after a phase of the `pardiso` routine and continue execution of the next phase.

### **Input Parameters**

|                |                                                                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dirname</i> | String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory. |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### **Output Parameters**

|           |                                                                  |
|-----------|------------------------------------------------------------------|
| <i>pt</i> | Array with a dimension of 64. Handle to internal data structure. |
|-----------|------------------------------------------------------------------|

|              |                      |
|--------------|----------------------|
| <i>error</i> | The error indicator. |
|--------------|----------------------|

| <b>error</b> | <b>Information</b>             |
|--------------|--------------------------------|
| 0            | No error.                      |
| -2           | Not enough memory.             |
| -10          | Cannot open file for reading.  |
| -11          | Error while reading from file. |
| -13          | Wrong file format.             |

## **pardiso\_handle\_delete**

*Delete files with pardiso internal structure data.*

---

### **Syntax**

```
void pardiso_handle_delete (const char *dirname, MKL_INT *error);
```

### **Include Files**

- mkl.h

## Description

This function deletes files generated with `pardiso_handle_store` that contain Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures.

## Input Parameters

|                      |                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dirname</code> | String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory. |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Output Parameters

|                    |                      |
|--------------------|----------------------|
| <code>error</code> | The error indicator. |
|--------------------|----------------------|

| <b><code>error</code></b> | <b>Information</b>   |
|---------------------------|----------------------|
| 0                         | No error.            |
| -10                       | Cannot delete files. |

## `pardiso_handle_store_64`

*Store internal structures from `pardiso_64` to a file.*

## Syntax

```
void pardiso_handle_store_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

## Include Files

- `mkl.h`

## Description

This function stores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures to a file, allowing you to store Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures between the stages of the `pardiso_64` routine. The `pardiso_handle_restore_64` routine can restore the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures from the file.

## Input Parameters

|                      |                                                                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pt</code>      | Array with a dimension of 64. Handle to internal data structure.                                                                                                                                                                                           |
| <code>dirname</code> | String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named <code>handle.pds</code> in the directory. |

## Output Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <code>pt</code> | Handle to internal data structure. |
|-----------------|------------------------------------|

|                    |                      |
|--------------------|----------------------|
| <code>error</code> | The error indicator. |
|--------------------|----------------------|

| <b><code>error</code></b> | <b>Information</b> |
|---------------------------|--------------------|
| 0                         | No error.          |

| <b>error</b> | <b>Information</b>                                                               |
|--------------|----------------------------------------------------------------------------------|
| -2           | Not enough memory.                                                               |
| -10          | Cannot open file for writing.                                                    |
| -11          | Error while writing to file.                                                     |
| -12          | Not supported in 32-bit library - routine is only supported in 64-bit libraries. |
| -13          | Wrong file format.                                                               |

## [pardiso\\_handle\\_restore\\_64](#)

*Restore pardiso\_64 internal structures from a file.*

---

### Syntax

```
void pardiso_handle_restore_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

### Include Files

- mkl.h

### Description

This function restores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures from a file. This allows you to restore Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures stored by `pardiso_handle_store_64` after a phase of the `pardiso_64` routine and continue execution of the next phase.

### Input Parameters

`dirname` String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

### Input Parameters

`pt` Array with a dimension of 64. Handle to internal data structure.

`error` The error indicator.

| <b>error</b> | <b>Information</b>             |
|--------------|--------------------------------|
| 0            | No error.                      |
| -2           | Not enough memory.             |
| -10          | Cannot open file for reading.  |
| -11          | Error while reading from file. |
| -13          | Wrong file format.             |

## [pardiso\\_handle\\_delete\\_64](#)

### Syntax

Delete files with `pardiso_64` internal structure data.

```
void pardiso_handle_delete_64 (const char *dirname, MKL_INT *error);
```

### Include Files

- `mkl.h`

### Description

This function deletes files generated with `pardiso_handle_store_64` that contain Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures.

### Input Parameters

|                      |                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dirname</code> | String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory. |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Output Parameters

|                           |                                                                                  |
|---------------------------|----------------------------------------------------------------------------------|
| <code>error</code>        | The error indicator.                                                             |
| <b><code>error</code></b> | <b>Information</b>                                                               |
| 0                         | No error.                                                                        |
| -10                       | Cannot delete files.                                                             |
| -12                       | Not supported in 32-bit library - routine is only supported in 64-bit libraries. |

### oneMKL PARDISO Parameters in Tabular Form

The following table lists all parameters of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and gives their brief descriptions.

| Parameter           | Type                  | Description                                                    | Values                    | Comments                                                                | In/Out |
|---------------------|-----------------------|----------------------------------------------------------------|---------------------------|-------------------------------------------------------------------------|--------|
| <code>pt</code>     | <code>void*</code>    | Solver internal data address pointer                           | 0                         | Must be initialized with zeros and never be modified later              | in/out |

### pardiso iparm Parameter

This table describes all individual components of the Intel® oneAPI Math Kernel Library (oneMKL) `PARDISO iparm` parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (\*).

| Component                                                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                     |   |                                                                   |    |                                                                              |

The preconditioner is $LL^T$ that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns. |            |             |    |                                                                                                  |    |                                                                                                  |    |                                                                                                                   |
| <p>The value <math>L</math> controls the stopping criterion of the Krylov Subspace iteration:<br/> <math>\text{eps}_{\text{CGS}} = 10^{-L}</math> is used in the stopping criterion<br/> <math>\ dx_i\  / \ dx_0\  &lt; \text{eps}_{\text{CGS}}</math><br/> where <math>\ dx_i\  = \ \text{inv}(L^*U)^*r_i\ </math> for <math>K = 1</math> or <math>\ dx_i\  = \ \text{inv}(L^*L^T)^*r_i\ </math> for <math>K = 2</math> and <math>r_i</math> is the residue at iteration <math>i</math> of the preconditioned Krylov Subspace iteration.</p> <p>A maximum number of 150 iterations is fixed with the assumption that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residue excursions are checked and can terminate the iteration process. If <math>phase = 23</math>, then the factorization for a given <math>A</math> is automatically recomputed in cases where the Krylov Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylov Subspace iteration is returned. Using <math>phase = 33</math> results in an error message (<math>error=-4</math>) if the stopping criteria for the Krylov Subspace iteration can not be reached. More information on the failure can be obtained from <a href="#">iparm[19]</a>.</p> <p>The default is <math>iparm[3]=0</math>, and other values are only recommended for an advanced user. <math>iparm[3]</math> must be greater than or equal to zero.</p> <p>Examples:</p> <table> <thead> <tr> <th><math>iparm[3]</math></th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>31</td> <td><math>LU</math>-preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices</td> </tr> <tr> <td>61</td> <td><math>LU</math>-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices</td> </tr> <tr> <td>62</td> <td><math>LL^T</math>-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices</td> </tr> </tbody> </table> |                                                                                                                                                                                                                                                                               | $iparm[3]$ | Description | 31 | $LU$ -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices | 61 | $LU$ -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices | 62 | $LL^T$ -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices |

|                           | <p>This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.</p> <p>This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of <math>P^* A^* P^T</math>), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the <i>perm</i> parameter.</p> |
|                           | <p><b>Caution</b><br/>           You can only set one of <i>iparm[4]</i>, <i>iparm[30]</i>, and <i>iparm[35]</i>, so be sure that the <i>iparm[30]</i> (partial solution) and the <i>iparm[35]</i> (Schur complement) parameters are 0 if you set <i>iparm[4]</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| input       | Intel® oneAPI Math Kernel Library (oneMKL) PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| input                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | This parameter controls the solve step of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector <i>defineperm</i> so that when <i>perm</i> ( <i>i</i> ) = 1 it means that either the <i>i</i> -th component in the right-hand sides is nonzero, or the <i>i</i> -th component in the solution vectors is computed, or both, depending on the value of <i>iparm</i> [30].<br><br>The permutation vector <i>perm</i> must be present in all phases of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO software. At the reordering step, the software overwrites the input vector <i>perm</i> by a permutation vector used by the software at the factorization and solver step. If <i>m</i> is the number of components such that <i>perm</i> ( <i>i</i> ) = 1, then the last <i>m</i> components of the output vector <i>perm</i> are a set of the indices <i>i</i> satisfying the condition <i>perm</i> ( <i>i</i> ) = 1 on input. |
| <b>NOTE</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Turning on this option often increases the time used by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step.                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Important</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| You can use this feature for both in-core and out-of-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as long as <i>iparm</i> [23]=1. Otherwise, you cannot use partial solve for out-of-core mode and you will need to set <i>iparm</i> [59]=0 for in-core mode. Set the parameters <i>iparm</i> [7] (iterative refinement steps), <i>iparm</i> [3] (preconditioned CGS), <i>iparm</i> [4] (user permutation), and <i>iparm</i> [35] (Schur complement) to 0 as well. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 0*                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Disables this option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <i>perm</i> is defined so that <i>perm</i> ( <i>i</i> ) = 1 means that the ( <i>i</i> )-th component in the right-hand sides is nonzero. In this case Intel® oneAPI Math Kernel Library (oneMKL) PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the <i>i</i> -th component in the solution vectors is only computed if <i>perm</i> ( <i>i</i> ) = 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <i>perm</i> is defined so that <i>perm</i> ( <i>i</i> ) = 1 means that the <i>i</i> -th component in the right-hand sides is nonzero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Component                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                                                                                                                                                                                                                                                                                                                                                                                                                                      | Unlike for $iparm[30]=1$ , all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for $iparm[30]=2$ you must set the $i$ -th component of the right-hand sides to zero explicitly if $perm(i)$ is not equal to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 3                                                                                                                                                                                                                                                                                                                                                                                                                                    | Selected components of the solution vectors are computed. The $perm$ array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case $perm(i) = 1$ means that the $i$ -th component in the solution vectors is computed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

You must also: <ul style="list-style-type: none"><li>• set <math>iparm[59]</math> to 0 in order to use the in-core version,</li><li>• not set <math>iparm[1]</math> to 3 in order to not use the parallel version of the nested dissection algorithm.</li></ul> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Otherwise Intel® oneAPI Math Kernel Library (oneMKL) PARDISO does not produce numerically repeatable results even if CNR is enabled for Intel® oneAPI Math Kernel Library (oneMKL) using the functionality described in <a href="#">Support Functions for CNR</a> .                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0*                                                                                                                                                                                                                                                                                                                                                                                                                                   | CNR mode for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO is enabled only if it is enabled for Intel® oneAPI Math Kernel Library (oneMKL) using the functionality described in <a href="#">Support Functions for CNR</a> and the in-core version is used. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO determines the optimal number of OpenMP threads automatically, and produces numerically reproducible results regardless of the number of threads.                                                                                                                                                                                                                                                                                                                                                     |
| >0                                                                                                                                                                                                                                                                                                                                                                                                                                   | CNR mode is enabled for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO if in-core version is used and the optimal number of OpenMP threads for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO to rely on is defined by the value of $iparm[33]$ . You can use $iparm[33]$ to enable CNR mode independent from other Intel® oneAPI Math Kernel Library (oneMKL) domains. To get the best performance, set $iparm[33]$ to the actual number of hardware threads dedicated for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. Setting $iparm[33]$ to fewer OpenMP threads than the maximum number of them in use reduces the scalability of the problem being solved. Setting $iparm[33]$ to more threads than are available can reduce the performance of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. |
| $iparm[34]$                                                                                                                                                                                                                                                                                                                                                                                                                          | One- or zero-based indexing of columns and rows.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <i>iparm[35]</i> | Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector <i>perm</i> to a set of indexes such that when <i>perm(i) = 1</i> , the <i>i</i> -th element of the initial matrix is an element of the Schur matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |    |                                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                                                                                                                                                                                                                                          |

Set it once again before calling the factorization phase. |
| 2                | Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |    |                                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                                                                                                                                                                                                                                          |

|-------------------|------------------------------------|
| <i>iparm</i> [63] | Rese<br>rv<br>. Set<br>to<br>zero. |

**NOTE**

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

**Parallel Direct Sparse Solver for Clusters Interface**

The Parallel Direct Sparse Solver for Clusters Interface solves large linear systems of equations with sparse matrices on clusters. It is

- high performing
- robust
- memory efficient
- easy to use

A hybrid implementation combines Message Passing Interface (MPI) technology for data exchange between parallel tasks (processes) running on different nodes, and OpenMP\* technology for parallelism inside each node of the cluster. This approach effectively uses modern hardware resources such as clusters consisting of nodes with multi-core processors. The solver code is optimized for the latest Intel processors, but also performs well on clusters consisting of non-Intel processors.

Code examples are available in the Intel® oneAPI Math Kernel Library (oneMKL) installation examples directory.

## Parallel Direct Sparse Solver for Clusters Interface Algorithm

Parallel Direct Sparse Solver for Clusters Interface solves a set of sparse linear equations

$$A^*X = B$$

with multiple right-hand sides using a distributed  $LU$ ,  $LL^T$ ,  $LDL^T$  or  $LDL^*$  factorization, where  $A$  is an  $n$ -by- $n$  matrix, and  $X$  and  $B$  are  $n$ -by- $nrhs$  matrices.

The solution comprises four tasks:

- analysis and symbolic factorization;
- numerical factorization;
- forward and backward substitution including iterative refinement;
- termination to release all internal solver memory.

The solver first computes a symmetric fill-in reducing permutation  $P$  based on the nested dissection algorithm from the METIS package [Karypis98](included with Intel® oneAPI Math Kernel Library (oneMKL)), followed by the Cholesky or other type of factorization (depending on matrix type)[Schenk00-2] of  $PAP^T$ . The solver uses either diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite or Hermitian matrices before finding an approximation of  $X$  by forward and backward substitution and iterative refinement.

The initial matrix  $A$  is perturbed whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal blocks. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricted notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. For a large set of matrices from different application areas, the accuracy of this method is comparable to a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Parallel Direct Sparse Solver for Clusters additionally improves the pivoting accuracy by applying symmetric weighted matching algorithms. These methods identify large entries in the coefficient matrix  $A$  that, if permuted close to the diagonal, enable the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. The methods are based on maximum weighted matching and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

## Parallel Direct Sparse Solver for Clusters Interface Matrix Storage

The sparse data storage in the Parallel Direct Sparse Solver for Clusters Interface follows the scheme described in the [Sparse Matrix Storage Formats](#) section using the variable  $ja$  for *columns*,  $ia$  for *rowIndex*, and  $a$  for *values*. Column indices  $ja$  must be in increasing order per row.

When an input data structure is not accessed in a call, a NULL pointer or any valid address can be passed as a placeholder for that argument.

## Algorithm Parallelization and Data Distribution

Intel® oneAPI Math Kernel Library (oneMKL) Parallel Direct Sparse Solver for Clusters enables parallel execution of the solution algorithm with efficient data distribution.

The master MPI process performs the symbolic factorization phase to represent matrix  $A$  as computational tree. Then matrix  $A$  is divided among all MPI processes in a one-dimensional manner. The same distribution is used for *L-factor* (the lower triangular matrix in Cholesky decomposition). Matrix  $A$  and all required internal data are broadcast to subordinate MPI processes. Each MPI process fills in its own parts of *L-factor* with initial values of the matrix  $A$ .

Parallel Direct Sparse Solver for Clusters Interface computes all independent parts of *L-factor* completely in parallel. When a block of the factor must be updated by other blocks, these updates are independently passed to a temporary array on each updating MPI process. It further gathers the result into an updated block using the `MPI_Reduce()` routine. The computations within an MPI process are dynamically divided among OpenMP threads using pipelining parallelism with a combination of left- and right-looking techniques similar to those of the PARDISO\* software. Level 3 BLAS operations from Intel® oneAPI Math Kernel Library (oneMKL) ensure highly efficient performance of block-to-block update operations.

During forward/backward substitutions, respective Right Hand Side (RHS) parts are distributed among all MPI processes. All these processes participate in the computation of the solution. Finally, the solution is gathered on the master MPI process.

This approach demonstrates good scalability on clusters with Infiniband\* technology. Another advantage of the approach is the effective distribution of *L-factor* among cluster nodes. This enables the solution of tasks with a much higher number of non-zero elements than it is possible with any Symmetric Multiprocessing (SMP) in-core direct solver.

The algorithm ensures that the memory required to keep internal data on each MPI process is decreased when the number of MPI processes in a run increases. However, the solver requires that matrix  $A$  and some other internal arrays completely fit into the memory of each MPI process.

To get the best performance, run one MPI process per physical node and set the number of OpenMP\* threads per node equal to the number of physical cores on the node.

---

#### **NOTE**

Instead of calling `MPI_Init()`, initialize MPI with `MPI_Init_thread()` and set the MPI threading level to `MPI_THREAD_FUNNELED` or higher. For details, see the code examples in `<install_dir>/examples`.

---

## **cluster\_sparse\_solver**

*Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.*

---

### **Syntax**

```
void cluster_sparse_solver (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT
*mnum, const MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a,
const MKL_INT *ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT
*iparm, const MKL_INT *msglvl, void *b, void *x, const int *comm, MKL_INT *error);
```

### **Include Files**

- `mkl_cluster_sparse_solver.h`

### **Description**

The routine `cluster_sparse_solver` calculates the solution of a set of sparse linear equations

```
A*X = B
```

with single or multiple right-hand sides, using a parallel  $LU$ ,  $LDL$ , or  $LL^T$  factorization, where  $A$  is an  $n$ -by- $n$  matrix, and  $X$  and  $B$  are  $n$ -by- $nrhs$  vectors or matrices.

**NOTE**

This routine supports the Progress Routine feature. See [Progress Function](#) for details.

**Input Parameters****NOTE**

Most of the input parameters (except for the *pt*, *phase*, and *comm* parameters and, for the distributed format, the *a*, *ia*, and *ja* arrays) must be set on the master MPI process only, and ignored on other processes. Other MPI processes get all required data from the master MPI process using the MPI communicator, *comm*.

| 13            | complex and nonsymmetric                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |                                 |   |                                      |    |                               |   |                                    |   |                                         |    |                                  |   |                       |    |                       |    |                          |
| <i>phase</i>  | Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Parallel Direct Sparse Solver for Clusters has the following phases of execution: <ul style="list-style-type: none"> <li>• Phase 1: Fill-reduction analysis and symbolic factorization</li> <li>• Phase 2: Numerical factorization</li> <li>• Phase 3: Forward and Backward solve including optional iterative refinement</li> <li>• Memory release (<i>phase</i>= -1)</li> </ul>                           |   |                                 |   |                                      |    |                               |   |                                    |   |                                         |    |                                  |   |                       |    |                       |    |                          |

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

| <i>phase</i> | <b>Solver Execution Steps</b>                                  |
|--------------|----------------------------------------------------------------|

*n*  
Number of equations in the sparse linear systems of equations  $A^*X = B$ .  
Constraint:  $n > 0$ .

*a*  
Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of *ja* for each row.

For CSR3 format, the size of *a* is the same as that of *ja*. Refer to the *values* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format the size of *a* is the size of *ja* multiplied by the square of the block size. Refer to the *values* array description in [Three Array Variation of BSR Format](#) for more details.

---

#### NOTE

For centralized input (*iparm[39]=0*), provide the *a* array for the master MPI process only. For distributed assembled input (*iparm[39]=1* or *iparm[39]=2*), provide it for all MPI processes.

---

---

#### Important

The column indices of non-zero elements of each row of the matrix *A* must be stored in increasing order.

---

*ia*  
For CSR3 format, *ia[i]* ( $i < n$ ) points to the first column index of row *i* in the array *ja*. That is, *ia[i]* gives the index of the element in array *a* that contains the first non-zero element from row *i* of *A*. The last element *ia[n]* is taken to be equal to the number of non-zero elements in *A*, plus one. Refer to *rowIndex* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format,  $ia[i]$  ( $i < n$ ) points to the first column index of row  $i$  in the array  $ja$ . That is,  $ia[i]$  gives the index of the element in array  $a$  that contains the first non-zero block from row  $i$  of  $A$ . The last element  $ia[n]$  is taken to be equal to the number of non-zero blocks in  $A$ , plus one. Refer to `rowIndex` array description in [Three Array Variation of BSR Format](#) for more details.

The array  $ia$  is accessed in all phases of the solution process.

Indexing of  $ia$  is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter `iparm[34]`. For zero-based indexing, the last element  $ia[n]$  is assumed to be equal to the number of non-zero elements in matrix  $A$ .

---

#### **NOTE**

For centralized input (`iparm[39]=0`), provide the  $ia$  array at the master MPI process only. For distributed assembled input (`iparm[39]=1` or `iparm[39]=2`), provide it at all MPI processes.

---

$ja$

For CSR3 format, array  $ja$  contains column indices of the sparse matrix  $A$ . It is important that the indices are in increasing order per row. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for `columns` array in [Three Array Variation of CSR Format](#).

For BSR3 format, array  $ja$  contains column indices of the sparse matrix  $A$ . It is important that the indices are in increasing order per row. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for `columns` array in [Three Array Variation of BSR Format](#).

The array  $ja$  is accessed in all phases of the solution process.

Indexing of  $ja$  is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter `iparm(35)`.

---

#### **NOTE**

For centralized input (`iparm(40)=0`), provide the  $ja$  array at the master MPI process only. For distributed assembled input (`iparm(40)=1` or `iparm(40)=2`), provide it at all MPI processes.

---

$perm$

Ignored.

$nrhs$

Number of right-hand sides that need to be solved for.

$iparm$

Array, size 64. This array is used to pass various parameters to Parallel Direct Sparse Solver for Clusters Interface and to return some useful information after execution of the solver.

See [cluster\\_sparse\\_solver iparm Parameter](#) for more details about the `iparm` parameters.

$msglvl$

Message level information. If  $msglvl = 0$  then `cluster_sparse_solver` generates no output, if  $msglvl = 1$  the solver prints statistical information to the screen.

Statistics include information such as the number of non-zero elements in *L-factor* and the timing for each phase.

Set *msglvl* = 1 if you report a problem with the solver, since the additional information provided can facilitate a solution.

*b*

Array, size *n\*nrhs*. On entry, contains the right-hand side vector/matrix *B*, which is placed in memory contiguously. The *b[i+k\*n]* must hold the *i*-th component of *k*-th right-hand side vector. Note that *b* is only accessed in the solution phase.

*comm*

MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the `MPI_Comm_c2f()` function. See the examples in the `<install_dir>/examples` directory.

## Output Parameters

*pt*

Handle to internal data structure.

*perm*

Ignored.

*iparm*

On output, some *iparm* values report information such as the numbers of non-zero elements in the factors.

See [cluster\\_sparse\\_solver iparm Parameter](#) for more details about the *iparm* parameters.

*b*

On output, the array is replaced with the solution if *iparm[5]* = 1.

*x*

Array, size (*n\*nrhs*). If *iparm[5]*=0 it contains solution vector/matrix *X*, which is placed contiguously in memory. The *x[i+k\*n]* element must hold the *i*-th component of the *k*-th solution vector. Note that *x* is only accessed in the solution phase.

*error*

The error indicator according to the below table:

| <b>error</b> | <b>Information</b>                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | no error                                                                                                                                                                                                                                                                                                                                                                                  |
| -1           | input inconsistent                                                                                                                                                                                                                                                                                                                                                                        |
| -2           | not enough memory                                                                                                                                                                                                                                                                                                                                                                         |
| -3           | reordering problem                                                                                                                                                                                                                                                                                                                                                                        |
| -4           | Zero pivot, numerical factorization or iterative refinement problem. If the error appears during the solution phase, try to change the pivoting perturbation ( <i>iparm[9]</i> ) and also increase the number of iterative refinement steps. If it does not help, consider changing the scaling, matching and pivoting options ( <i>iparm[10]</i> , <i>iparm[12]</i> , <i>iparm[20]</i> ) |
| -5           | unclassified (internal) error                                                                                                                                                                                                                                                                                                                                                             |

## cluster\_sparse\_solver\_64

*Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.*

### Syntax

```
void cluster_sparse_solver_64 (_MKL_DSS_HANDLE_t pt, const long long int *maxfct, const
long long int *mnum, const long long int *mtype, const long long int *phase, const long
long int *n, const void *a, const long long int *ia, const long long int *ja, long long
int *perm, const long long int *nrhs, long long int *iparm, const long long int
*msglvl, void *b, void *x, const int *comm, long long int *error);
```

### Include Files

- mkl\_cluster\_sparse\_solver.h

### Description

The routine `cluster_sparse_solver_64` is an alternative ILP64 (64-bit integer) version of the `cluster_sparse_solver` routine (see the Description section for more details). The interface of `cluster_sparse_solver_64` is the same as the interface of `cluster_sparse_solver`, but it accepts and returns all integer data as `long long int`.

Use `cluster_sparse_solver_64` when `cluster_sparse_solver` for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel® oneAPI Math Kernel Library (oneMKL) functionality. In other words, if you use 64-bit integer version (`cluster_sparse_solver_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `cluster_sparse_solver_64` may perform slower than regular `cluster_sparse_solver` on the reordering and symbolic factorization phase.

---

#### NOTE

`cluster_sparse_solver_64` is supported only in the 64-bit libraries. If `cluster_sparse_solver_64` is called from the 32-bit libraries, it returns `error = -12`.

---

---

#### NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) for details.

---

### Input Parameters

The input parameters of `cluster_sparse_solver_64` are the same as the input parameters of `cluster_sparse_solver`, but `cluster_sparse_solver_64` accepts all integer data as `long long int`.

## Output Parameters

The output parameters of `cluster_sparse_solver_64` are the same as the output parameters of `cluster_sparse_solver`, but `cluster_sparse_solver_64` returns all integer data as `long long int`.

### `cluster_sparse_solver_get_csr_size`

*Computes the (local) number of rows and (local) number of nonzero entries for (distributed) CSR data corresponding to the provided name.*

---

#### Syntax

```
void cluster_sparse_solver_get_csr_size (_MKL_DSS_HANDLE_t pt, _MKL_DSS_EXPORT_DATA
name , MKL_INT *local_nrows, MKL_INT *local_nnz, const int*comm, MKL_INT *error);
```

#### Include Files

- `mkl_cluster_sparse_solver.h`

#### Description

This routine uses the internal data created during the factorization phase of `cluster_sparse_solver` for matrix  $A$ . The routine then:

- Computes the local number of rows and the local number of nonzeros for CSR data that correspond to the provided *name*
- Returns the computed values in `local_nrows` and `local_nnz`

It is assumed that the CSR data defined by the *name* will be distributed in the same way as the matrix  $A$  (as defined by `iparm[39]`) used in `cluster_sparse_solver`.

The returned values can be used for allocating CSR arrays for factors  $L$  and  $U$ , and also for allocating arrays for permutations  $P$  and  $Q$ , or scaling matrix  $D$  which can then be used with

`cluster_sparse_solver_set_csr_ptrs` or `cluster_sparse_solver_set_ptr` for exporting corresponding data via `cluster_sparse_solver_export`.

---

#### NOTE

Only call this routine after the factorization phase (*phase=22*) of the `cluster_sparse_solver` has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to `cluster_sparse_solver`.

---

## Input Parameters

|           |                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>pt</i> | Array with size of 64.<br>Handle to internal data structure used in the prior calls to <code>cluster_sparse_solver</code> . |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|

---

#### Caution

Do not modify *pt* after the calls to `cluster_sparse_solver`.

---

|             |                                                              |
|-------------|--------------------------------------------------------------|
| <i>name</i> | Specifies CSR data for which the output values are computed. |
|-------------|--------------------------------------------------------------|

SPARSE\_PTLUQT\_L     Factor  $L$  from  $P^*A^*Q=L^*U$ .

|                    |                  |                                                                                                                                                                                                                                                 |
|--------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | SPARSE_PTLUQT_U  | Factor $U$ from $P^* A^* Q = L^* U$ .                                                                                                                                                                                                           |
|                    | SPARSE_DPTLUQT_L | Factor $L$ from $P^* (D^{-1}A) * Q = L^* U$ .                                                                                                                                                                                                   |
|                    | SPARSE_DPTLUQT_U | Factor $U$ from $P^* (D^{-1}A) * Q = L^* U$ .                                                                                                                                                                                                   |
| <i>local_nrows</i> |                  | On entry, an array of size 1.                                                                                                                                                                                                                   |
| <i>local_nnz</i>   |                  | On entry, an array of size 1.                                                                                                                                                                                                                   |
| <i>comm</i>        |                  | MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the <code>MPI_Comm_c2f()</code> function. See the examples in the <code>&lt;install_dir&gt;/examples</code> directory. |

## Output Parameters

*local\_nrows* On output, the local number of rows for the CSR data which correspond to the *name*.

*local\_nnz* On output, the local number of nonzero entries for the CSR data which correspond to the *name*.

*error* The error indicator:

| <b>error</b> | <b>Information</b>                                                                                                                                 |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | no error                                                                                                                                           |
| -1           | <i>pt</i> is a null pointer                                                                                                                        |
| -2           | invalid <i>pt</i>                                                                                                                                  |
| -3           | invalid <i>name</i>                                                                                                                                |
| -4           | unsupported <i>name</i>                                                                                                                            |
| -9           | unsupported internal code path, consider switching off non-default <i>iparm</i> parameters for <code>cluster_sparse_solver</code>                  |
| -10          | unsupported case when the matrix <i>A</i> is distributed among processes with overlap in the preceding calls to <code>cluster_sparse_solver</code> |
| -12          | internal memory error                                                                                                                              |

---

**NOTE** Refer to `cl_solver_export_c.c` for an example using this functionality.

---

## cluster\_sparse\_solver\_set\_csr\_ptrs

Saves internally-provided pointers to the 3-array CSR data corresponding to the specified name.

---

### Syntax

```
void cluster_sparse_solver_set_csr_ptrs (_MKL_DSS_HANDLE_t pt, _MKL_DSS_EXPORT_DATA
name, MKL_INT *rowptr, MKL_INT *colindx, void *vals, const int *comm, MKL_INT *error);
```

## Description

This routine internally saves the input pointers, *rowptr*, *colindx*, and *vals*, of the 3-array CSR data, which correspond to the provided *name*. It is assumed that the exported data will be distributed in the same way as the matrix *A* (as defined by *iparm[39]*) used in *cluster\_sparse\_solver*.

The saved pointers can then be used for exporting corresponding data by means of *cluster\_sparse\_solver\_export*.

---

### NOTE

Only call this routine after the factorization phase (*phase=22*) of the *cluster\_sparse\_solver* has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to *cluster\_sparse\_solver*.

---

## Input Parameters

|                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                                                                           | SPARSE_DPTLUQT_U      Factor <i>U</i> from $P^* (D^{-1}A)^* Q = L^* U$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>rowptr</i>                                                             | Array of length at least ( <i>local_nrows</i> +1) where <i>local_nrows</i> is the local number of rows, which can be obtained by calling <i>cluster_sparse_solver_get_csr_size</i> . This array contains row indices, such that <i>rowptr[i] - indexing</i> is the first index of row <i>i</i> in the array's <i>vals</i> and <i>colindx</i> . Here, the value of <i>indexing</i> is 0 for zero-based indexing and 1 for one-based indexing, and must be the same as it was for the matrix <i>A</i> used in the preceding calls to <i>cluster_sparse_solver</i> (also stored in <i>iparm[34]</i> ).<br>Refer to <i>pointerB</i> array description in <a href="#">CSR Format</a> for more details. |
| <i>colindx</i>                                                            | Array of length at least <i>rowptr[local_nrows] - rowptr[0]</i> . Indexing (zero- or one-based) must be the same as for <i>rowptr</i> . For one-based indexing, the array contains the column indices plus one for each non-zero element of the matrix which corresponds to the <i>name</i> . For zero-based indexing, the array contains the column indices for each non-zero element of the matrix.                                                                                                                                                                                                                                                                                             |

---

|             |                                                                                                                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vals</i> | Array containing non-zero elements of the matrix which corresponds to the <i>name</i> . Its length is equal to length of the <i>colindx</i> array. Refer to values array description in <a href="#">CSR Format</a> for more details.                     |
|             | It will be interpreted internally as <code>float*/double*(MKL_Complex8*/MKL_Complex16*)</code> depending on <i>mtype</i> (type of the matrix A) and <i>iparm[27]</i> (precision) specified in the preceding call to <code>cluster_sparse_solver</code> . |
| <i>comm</i> | MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the <code>MPI_Comm_c2f()</code> function. See the examples in the <code>&lt;install_dir&gt;/examples</code> directory.          |

## Output Parameters

*error* The error indicator:

| <b>error</b> | <b>Information</b>                                                                                                                |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 0            | no error                                                                                                                          |
| -1           | <i>pt</i> is a null pointer                                                                                                       |
| -2           | invalid <i>pt</i>                                                                                                                 |
| -3           | invalid <i>name</i>                                                                                                               |
| -4           | unsupported <i>name</i>                                                                                                           |
| -9           | unsupported internal code path, consider switching off non-default <i>iparm</i> parameters for <code>cluster_sparse_solver</code> |
| -12          | internal memory error                                                                                                             |

---

**NOTE** Refer to `cl_solver_export_c.c` for an example using this functionality.

---

## [cluster\\_sparse\\_solver\\_set\\_ptr](#)

*Internally saves a provided pointer to the data corresponding to the specified name.*

---

### Syntax

```
void cluster_sparse_solver_set_ptr (_MKL_DSS_HANDLE_t pt, _MKL_DSS_EXPORT_DATA name,
void *ptr, const int *comm, MKL_INT *error);
```

### Include Files

- `mkl_cluster_sparse_solver.h`

### Description

This routine internally saves the input pointer, *ptr*, of the data which correspond to the provided *name*. The saved pointer can then be used for exporting corresponding data by means of `cluster_sparse_solver_export`.

**NOTE**

Only call this routine after the factorization phase (*phase*=22) of the `cluster_sparse_solver` has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to `cluster_sparse_solver`.

---

**Input Parameters**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>pt</i>   | Array with size of 64.<br>Handle to internal data structure used in the prior calls to <code>cluster_sparse_solver</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <hr/>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | <b>Caution</b><br>Do not modify <i>pt</i> after the calls to <code>cluster_sparse_solver</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| -9           | unsupported internal code path, consider switching off non-default <i>iparm</i> parameters for <i>cluster_sparse_solver</i> |
| -12          | internal memory error                                                                                                       |

---

**NOTE** Refer to `cl_solver_export_c.c` for an example using this functionality.

---

## cluster\_sparse\_solver\_export

*Computes data corresponding to the specified decomposition (defined by export operation) and fills the pointers provided by calls to cluster\_sparse\_solver\_set\_ptr and/or cluster\_sparse\_solver\_set\_csr\_ptrs.*

---

### Syntax

```
void cluster_sparse_solver_export (_MKL_DSS_HANDLE_t pt, _MKL_DSS_EXPORT_OPERATION
operation, const int *comm, MKL_INT *error);
```

### Include Files

- `mkl_cluster_sparse_solver.h`

### Description

This routine computes the data for the pointers of the (distributed) data to be exported (as defined the specified *operation*). It is assumed that the exported data will be distributed in the same way as the matrix *A* (as defined by *iparm[39]*) used in `cluster_sparse_solver`.

---

#### NOTE

Only call this routine after the factorization phase (*phase=22*) of the `cluster_sparse_solver` has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to `cluster_sparse_solver`.

---

---

#### NOTE

Only call this routine after all pointers to the data required for the specified operation have been provided by means of calling `cluster_sparse_solver_set_ptr` and/or `cluster_sparse_solver_set_csr_ptrs`.

---

### Input Parameters

- |           |                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>pt</i> | Array with size of 64.<br>Handle to internal data structure used in the prior calls to <code>cluster_sparse_solver</code> . |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|

**Caution**

Do not modify  $pt$  after the calls to `cluster_sparse_solver`.

---

*operation*

|                             |                                                                      |
|-----------------------------|----------------------------------------------------------------------|
| <code>SPARSE_PTLUQT</code>  | Exporting data from decomposition $P^* A^* Q = L^* U$ .              |
| <code>SPARSE_DPTLUQT</code> | Exporting data from decomposition from $P^* (D^{-1}A)^* Q = L^* U$ . |

**NOTE**

Currently, for `operation=SPARSE_DPTLUQT` a real (complex) unit vector is provided for the scaling matrix  $D$ . Do not turn on scaling(`iparm[10]>0`) or matching(`iparm[12]>0`) in the `iparm` during the call to `cluster_sparse_solver` for this value of `operation`.

---

*comm*

MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the `MPI_Comm_c2f()` function. See the examples in the `<install_dir>/examples` directory.

## Output Parameters

*error*

The error indicator:

| <b>error</b> | <b>Information</b>                                                                                                                                          |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | no error                                                                                                                                                    |
| -1           | $pt$ is a null pointer                                                                                                                                      |

## cluster\_sparse\_solver iparm Parameter

The following table describes all individual components of the Parallel Direct Sparse Solver for Clusters Interface *iparm* parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (\*).

| Component                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| input                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 2*     The nested dissection algorithm from the METIS package [Karypis98].<br>3       The parallel version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Phase 1 takes significant time.<br>10      The MPI version of the nested dissection and symbolic factorization algorithms for the matrix in distributed assembled matrix input format ( <i>iparm</i> [39] > 0). The input matrix for the reordering must be distributed among different MPI processes without any intersection and all MPI ranks must have at least one row of the input matrix. Use <i>iparm</i> [40] and <i>iparm</i> [41] to set the bounds of the domain. During all of Phase 1, the entire matrix is not gathered on any one process, which can decrease computation time (especially when Phase 1 takes significant time) and decrease memory usage for each MPI process on the cluster. |
| <b>NOTE</b> Distributed reordering does not work if any of matching ( <i>iparm</i> [12]=1) / scaling ( <i>iparm</i> [10]=1) / BSR format ( <i>iparm</i> [36]>1) / Schur complement matrix computation control ( <i>iparm</i> [35]>0) / Partial solve ( <i>iparm</i> [30] > 0) is turned on, or if the distributed input matrix has overlapping distribution of rows across MPI processes.                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>NOTE</b><br>If you set <i>iparm</i> [1] = 10, <i>comm</i> = -1 (MPI communicator), and if there is one MPI process, optimization and full parallelization with the OpenMP version of the nested dissection and symbolic factorization algorithms proceeds. This can decrease computation time on multi-core computers. In this case, set <i>iparm</i> [40] = 1 and <i>iparm</i> [41] = <i>n</i> for one-based indexing, or to 0 and <i>n</i> - 1, respectively, for zero-based indexing. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>iparm</i> [2]                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Reserved. | input                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.<br><br>This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of $P^* A^* P^T$ ), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the <i>perm</i> parameter.                                                                                                                                                                                      |

| Component                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |    |                                                                                                                                            |    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |    |                                                                                                                                                                                                                                                                        |

|                                                                                                | <p>This parameter instructs Parallel Direct Sparse Solver for Clusters Interface how to handle small pivots or zero pivots for nonsymmetric matrices (<math>mtype = 11</math> or <math>mtype = 13</math>) and symmetric matrices (<math>mtype = -2</math>, <math>mtype = -4</math>, or <math>mtype = 6</math>). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].</p> <p>Small pivots are perturbed with <math>\text{eps} = 10^{-iparm[9]}</math>.</p> <p>The magnitude of the potential pivot is tested against a constant threshold of <math>\text{alpha} = \text{eps} *   A_2  _{\infty}</math>, where <math>\text{eps} = 10^{(-iparm[9])}</math>, <math>A_2 = P^* P_{MPS}^* D_r^* A^* D_c^* P</math>, and <math>  A_2  _{\infty}</math> is the infinity norm of the scaled and permuted matrix <math>A</math>. Any tiny pivots encountered during elimination are set to the sign <math>(l_{II})^* \text{eps} *   A_2  _{\infty}</math>, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with <math>\text{eps} = 10^{(-iparm[9])}</math>.</p> |

| input                              | Parallel Direct Sparse Solver for Clusters Interface can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.                                                                                                                                                                                                                                                                                                                                                                                                         |    |                                                                                      |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| input                                 | This parameter controls the solve step of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector <i>defineperm</i> so that when <i>perm(i)</i> = 1 it means that either the <i>i</i> -th component in the right-hand sides is nonzero, or the <i>i</i> -th component in the solution vectors is computed, or both, depending on the value of <i>iparm</i> [30].<br><br>The permutation vector <i>perm</i> must be present in all phases of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO software. At the reordering step, the software overwrites the input vector <i>perm</i> by a permutation vector used by the software at the factorization and solver step. If <i>m</i> is the number of components such that <i>perm(i)</i> = 1, then the last <i>m</i> components of the output vector <i>perm</i> are a set of the indices <i>i</i> satisfying the condition <i>perm(i)</i> = 1 on input. |    |                                                                                                                  |   |                                                                                                                                                                       |

| 1                                                                                                                                                                                                                                     | it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <i>perm</i> is defined so that <i>perm(i)</i> = 1 means that the ( <i>i</i> )-th component in the right-hand sides is nonzero. In this case Intel® oneAPI Math Kernel Library (oneMKL) PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the <i>i</i> -th component in the solution vectors is only computed if <i>perm(i)</i> = 1.                                |
| 2                                                                                                                                                                                                                                     | It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <i>perm</i> is defined so that <i>perm(i)</i> = 1 means that the <i>i</i> -th component in the right-hand sides is nonzero.<br>Unlike for <i>iparm[30]</i> =1, all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for <i>iparm[30]</i> =2 you must set the <i>i</i> -th component of the right-hand sides to zero explicitly if <i>perm(i)</i> is not equal to 1. |
| 3                                                                                                                                                                                                                                     | Selected components of the solution vectors are computed. The <i>perm</i> array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case <i>perm(i)</i> = 1 means that the <i>i</i> -th component in the solution vectors is computed.                                                                                                                                                                                                                                                                   |

| 2                                   | Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |    |                                                                                                                                  |   |                                                                                                                                                                                                                                                                                             |     |                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                                                                                                                                                                                                           |

| 3                                   | Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix <i>A</i> data. Set the bounds of the domain using <i>iparm[40]</i> and <i>iparm[41]</i> . The <i>A</i> and RHS elements are distributed between processes in same manner and the solution vector is the same on each process                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |    |                                                                                                                                  |   |                                                                                                                                                                                                                                                                                             |     |                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                                                                                                                                                                                                           |
| <i>iparm[40]</i>                    | Beginning of input domain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |    |                                                                                                                                  |   |                                                                                                                                                                                                                                                                                             |     |                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                                                                                                                                                                                                           |
| input                               | The number of the matrix <i>A</i> row, RHS element, and, for <i>iparm[39]</i> =2, solution vector that begins the input domain belonging to this MPI process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                  |   |                                                                                                                                                                                                                                                                                             |     |                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                                                                                                                                                                                                           |
